Reprint Courtesy of International Business Machines Corporation, © 2015 International Business Machines Corporation

INTERNATIONAL BUSINESS MACHINES CORPORATION (IBM) ARMONK, NEW YORK 10504

PERMISSION TO REPRINT IBM COPYRIGHTED PUBLICATIONS

Each reprint must be accompanied by the following credit line: **“Reprint Courtesy of International Business Machines Corporation, © (year) International Business Machines Corporation”**. The credit line normally should appear on the page where the reprint appears, either under the title or as a footnote.

If the foregoing is inconvenient, the credit line may be placed on the face or back of the title page (or front cover, if there is no title page) or in a conveniently viewable manner with suitable reference to the place where the reprint appears.

When multiple IBM materials are reprinted in the same publication, a consolidated credit paragraph may be used on the title page, or in a conveniently viewable manner listing the titles, corresponding copyright notices and references to the points where the reprints appear.

It is the understanding of **International Business Machines Corporation** that the purpose for which its material is being used is accurate and true as stated in the original request.

Permission to quote from, transmit electronically or reprint IBM material is limited to the purpose and quantities originally requested and must not be construed as a blanket license to use the material for other purposes or to reprint other IBM copyrighted material.

IBM reserves the right to withdraw permission to use copyrighted material whenever, in its discretion, it feels that the privilege of using its material is being used in a way detrimental to its interest or the above instructions are not being followed properly to protect its copyright.

No permission is granted to use trademarks of **International Business Machines Corporation** and its affiliates apart from the incidental appearance of such trademarks in the titles, text, and illustrations of the named publications. Any proposed use of trademarks apart from such incidental appearance requires separate approval in writing and ordinarily cannot be given. The use of any IBM trademark should not be of a manner which might cause confusion of origin or appear to endorse non-IBM products.

THIS PERMISSION IS PROVIDED WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING BUT NOT LIMITED TO IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE.

Presentation Manager Programming Guide and Reference

IBM OS/2 Toolkit Documentation

How to Use this Book

This reference is a detailed technical guide and reference for application programmers. It gives reference information and code examples to enable you to write source code using Presentation Manager functions.

Before you begin to use this information, it would be helpful to understand how you can:

- Expand the Contents to see all available topics
- Obtain additional information for a highlighted word or phrase
- Use action bar choices
- Use the programming information

How to Use the Contents

When the Contents window first appears, some topics have a plus (+) sign beside them. The plus sign indicates that additional topics are available.

To expand the Contents if you are using a mouse, click on the plus sign. If you are using the keyboard, use the Up or Down Arrow key to highlight the topic, and press the plus (+) key. For example, **Code Pages** has a plus sign beside it. To see additional topics for that heading, click on the plus sign or highlight that topic and press the plus (+) key.

To view a topic, double-click on the topic (or press the Up or Down Arrow key to highlight the topic, and then press the Enter key).

How to Obtain Additional Information

After you select a topic, the information for that topic appears in a window. Highlighted words or phrases indicate that additional information is available. You will notice that certain words and phrases are highlighted in green letters, or in white letters on a black background. These are called hypertext terms. If you are using a mouse, double-click on the highlighted word. If you are using a keyboard, press the Tab key to move to the highlighted word, and then press the Enter key. Additional information then appears in a window.

How to Use Action Bar Choices

Several choices are available for managing information presented in the *Presentation Manager Programming Reference*. There are three pull-down menus on the action bar: the **Services** menu, the **Options** menu, and the **Help** menu.

The actions that are selectable from the **Services** menu operate on the active window currently displayed on the screen. These actions include the following:

Bookmark

Allows you to set a placeholder so you can retrieve information of interest to you.

When you place a bookmark on a topic, it is added to a list of bookmarks you have previously set. You can view the list, and you can remove one or all bookmarks from the list. If you have not set any bookmarks, the list is empty.

To set a bookmark, do the following:

1. Select a topic from the Contents.
2. When that topic appears, choose the **Bookmark** option from the **Services** pull-down.
3. If you want to change the name used for the bookmark, type the new name in the field.
4. Click on the **Place** radio button (or press the Up or Down Arrow key to select it).
5. Click on **OK** (or select it and press Enter). The bookmark is then added to the bookmark list.

Search

Allows you to find occurrences of a word or phrase in the current topic, selected topics, or all topics.

You can specify a word or phrase to be searched. You can also limit the search to a set of topics by first marking the topics in the Contents list.

To search for a word or phrase in all topics, do the following:

1. Choose the **Search** option from the **Services** pull-down.
2. Type the word or words to be searched for.
3. Click on **All sections** (or press the Up or Down Arrow keys to select it).

4. Click on **Search** (or select it and press Enter) to begin the search.
5. The list of topics where the word or phrase appears is displayed.

Print

Allows you to print one or more topics. You can also print a set of topics by first marking the topics in the Contents list.

To print the document Contents list, do the following:

1. Choose **Print** from the **Services** pull-down.
2. Click on **Contents** (or press the Up or Down Arrow key to select it).
3. Click on **Print** (or select it and press Enter).
4. The Contents list is printed on your printer.

Copy

Allows you to copy a topic that you are viewing to the System Clipboard or to a file that you can edit. You will find this particularly useful for copying syntax definitions and program samples into the application that you are developing.

You can copy a topic that you are viewing in two ways:

- **Copy** copies the topic that you are viewing into the System Clipboard. If you are using a Presentation Manager editor (for example, the System Editor) that copies or cuts (or both) to the System Clipboard, and pastes to the System Clipboard, you can easily add the copied information to your program source module.
- **Copy to file** copies the topic that you are viewing into a temporary file named TEXT.TMP. You can later edit that file by using any editor. You will find TEXT.TMP in the directory where your viewable document resides.

To copy a topic, do the following:

1. Expand the Contents list and select a topic.
2. When the topic appears, choose **Copy to file** from the **Services** pull-down.
3. The system puts the text pertaining to that topic into the temporary file named TEXT.TMP.

For information on one of the other choices in the **Services** pull-down, highlight the choice and press the F1 key.

The actions that are selectable from the **Options** menu allow you to change the way your Contents list is displayed. To expand the Contents and show all levels for all topics, choose **Expand all** from the **Options** pull-down. You can also press the Ctrl and * keys together. For information on one of the other choices in the **Options** pull-down, highlight the choice and press the F1 key.

The actions that are selectable from the **Help** menu allow you to select different types of help information. You can also press the F1 key for help information about the Information Presentation Facility (IPF).

How to Use the Programming Information

This document consists of guide and reference information that provides a detailed description of each function, message, constant, and data type. It provides language-dependent information about the functions which enable the user to generate call statements in the C Language.

Presentation Manager programming information is presented by component, such as Device Functions, Direct Manipulation Functions, and Font-File format, for example:

Contents

- + Device Functions
- + Direct Manipulation Functions
- + Font-File Format

By clicking on the plus sign beside "Device Functions", you see an alphabetic list of the Presentation Manager Device functions. Selecting a function takes you directly into the reference information for that function.

Units of reference information are presented in selectable multiple windows or viewports. A viewport is a Presentation Manager window that can be sized, moved, minimized, maximized, or closed. By selecting a unit (in this case, an entry on the Contents list), you will see two windows displayed:

Unit Title	Selection Title
Select an item	
Syntax	
Returns	
Notes	
Example Code	
Related Functions	
Glossary	

The window on the left is the primary window. It contains a list of items that are always available to you. The window on the right is the secondary window. It contains a "snapshot" of the unit information. For reference units (that is, function descriptions), this window contains the Function Syntax.

All of the information needed to understand a reference unit (or topic) is readily available to you through the primary window. The information is divided into discrete information groups, and only the appropriate information group appears for the topic that you are viewing.

The information groups for a reference unit (that is, a function description) can include all or some of the following:

- Syntax
- Parameters
- Returns
- Errors
- Notes
- Example Code
- Related Functions
- Graphic Elements and Orders
- Glossary

This list may vary. Some topics may be omitted when they do not apply.

Information groups are displayed in separate viewports that are stacked in a third window location that overlaps the secondary window. By selecting an item (information group) in the primary window, the item is displayed in the third window location, as follows:

Unit Title	Selection	Glossary
Select an item		Select a starting letter of glossary terms
.		
.		
.	A	N
.	B	O
.	C	P
Glossary	.	.
	.	.
	.	.
	M	Z

By selecting successive items from the primary window, additional windows are displayed on top of the previous windows displayed in the third window location. For example, in a function description, Parameters and Return Values are items listed in the primary window. When selected, they appear one on top of the other in the third window location. Because of this, you may move the first selected (topmost) window to the left before selecting the next item. This allows simultaneous display of two related pieces of information from the "stack" of windows in the third window location, as follows:

Unit Title	Parameters	Return Values
Select an item		
.		
.		
.		
Returns		
Errors		
.		
.		
.		

Each window can be individually closed from its system menu. All windows are closed when you close the primary window.

Some secondary windows may have the appearance of a split screen. For example, an illustration may appear in the left half of the window, and scrollable, explanatory information may appear in the right half of the window. Because illustrations may not necessarily fit into the small window size on your screen, you may maximize the secondary window for better readability.

Conventions Used in this Book

The purpose of this reference is to give important information about functions, messages, constants, and data types. It provides language-dependent information about the functions which enables the user to call functions in the C programming language.

The following information is provided:

- The syntax and parameters for each function
- The syntax of each data type and structure

Notation Conventions

The following notation conventions are used in this reference:

NULL	The term NULL applied to a parameter is used to indicate the presence of the pointer parameter, but with no value.										
NULLHANDLE	The term NULLHANDLE applied to a parameter is used to indicate the presence of the handle parameter, but with no value.										
Implicit Pointer	If no entry for a data type "Pxxxxxx" is found in then it is implicitly a pointer to the data type "xxxxxx". See Implicit Pointer Data Types for more information about implicit pointers.										
Constant Names	<p>All constants are written in uppercase to match the header files. Where applicable, constant names have a prefix derived from the name of a function, message, or idea associated with the constant. For example:</p> <table><tr><td>WM_CREATE</td><td>Window message</td></tr><tr><td>SV_CXICON</td><td>System value</td></tr><tr><td>CF_TEXT</td><td>Clipboard format.</td></tr></table> <p>In this book, references to a complete set of constants with a given prefix is written as shown in the following examples:</p> <table><tr><td>Window message</td><td>WM_*</td></tr><tr><td>System value</td><td>SV_*</td></tr></table>	WM_CREATE	Window message	SV_CXICON	System value	CF_TEXT	Clipboard format.	Window message	WM_*	System value	SV_*
WM_CREATE	Window message										
SV_CXICON	System value										
CF_TEXT	Clipboard format.										
Window message	WM_*										
System value	SV_*										
Parameters and Fields	Function parameters and data structure fields are shown in italics.										

Conventions Used in Function Descriptions

The documentation of each function contains these sections:

Syntax

The function syntax describes the C-language calling syntax of the function and gives a brief description.

Programming Note

The functions in this book are spelled in mixed-case for readability but are known to the system as uppercase character strings. For example, the function "GPIBeginArea" is actually the external name "GPIBEGINAREA".

If you are using a compiler that generates a mixed-case external name, you should code the functions in uppercase.

Parameters

Each parameter is listed with its C-language data type, parameter type, and a brief description.

- All data types are written in uppercase to match the header files. A data type of "Pxxxxxxx" implicitly defines a pointer to the data type "xxxxxxx".

The term NULL applied to a parameter indicates the presence of the parameter, with no value.

Refer to for a complete list of all data types and their descriptions.

- There are three parameter types:

Input	Specified by the programmer.
Output	Returned by the function.
Input/Output	Specified by the programmer and modified by the function.

- A brief description is provided with each parameter. Where appropriate, restrictions are also included. In some cases, the parameter points to a structure.

Returns

A list of possible return codes or errors (when appropriate) is included in this section. Some functions do not have return codes. Refer to for a list of error codes and their numerical values, and for a list of error codes and their descriptions.

For some functions, this section includes a statement that the function requires a message queue. This means that, before issuing a call, [WinCreateMsgQueue](#) must be issued by the same thread. For other functions, no previous [WinCreateMsgQueue](#) is required, and it is only necessary to issue [WinInitialize](#) from the same thread.

Remarks

This section contains additional information about the function, when required.

Related Functions

This list shows the functions (if any) that are related to the function being described.

Example Code

An example of how the function can be used is shown in C language.

Error Severities

Each of the error conditions given in the list of errors for each function falls into one of these areas:

Warning

The function detected a problem, but took some remedial action that enabled the function to complete successfully. The return code in this case indicates that the function completed successfully.

Error

The function detected a problem for which it could not take any sensible remedial action. The system has recovered from the problem, and the state of the system, with respect to the application, remains the same as at the time when the function was requested. The system has not even partially executed the function (other than reporting the error).

Severe Error

The function detected a problem from which the system could not reestablish its state, with respect to the application, at the time when that function was requested; that is, the system partially executed the function. This necessitates the application performing some corrective activity to restore the system to some known state.

Unrecoverable Error

The function detected some problem from which the system could not re-establish its state, with respect to the application, at the time when that call was issued. It is possible that the application cannot perform some corrective action to restore the system to some

known state.

The [WinGetLastError](#) and [WinGetErrorInfo](#) functions can be used to find out more about an error (or warning) that occurs as a result of executing a call.

Header Files

All functions require an "#include" statement for the system header file OS2.H:

```
#include <OS2.H>
```

Most functions also require a "#define" statement to select an appropriate (conditional) section of the header file, and hence, the required prototype. Where this is necessary, it is shown at the head of the function definition in the form:

```
#define INCL_name
```

Note: These "#define" statements must precede the "#include <OS2.H>" statement.

Helper Macros

A series of macros is defined for packing data into, and extracting data from, variables of [MPARAM](#) and [MRESULT](#) data types. They are used in conjunction with the [WinSendMsg](#) and the other message functions, and also inside window and dialog procedures.

These macros always cast their arguments to the specified type, so values of any of the types specified for each macro can be passed without additional casting. NULL can be used to pass unused parameter data.

Macros for packing data into a [MPARAM](#) variable are shown below:

```
/* Used to pass any pointer type: */
#define MPFROMP(p) ((MPARAM)(VOID*)(p))

/* Used to pass a window handle: */
#define MPFROMHWND(hwnd) ((MPARAM)(HWND)(hwnd))

/* Used to pass a CHAR, UCHAR, or BYTE: */
#define MPFROMCHAR(ch) ((MPARAM)(USHORT)(ch))

/* Used to pass a LONG, ULONG, or BOOL: */
#define MPFROMLONG(l) ((MPARAM)(ULONG)(l))

/* Used to pass two SHORTs or USHORTs: */
#define MPFROM2SHORT(s1, s2) ((MPARAM)MAKELONG(s1, s2))

/* Used to pass a SHORT and 2 UCHARs: (WM_CHAR msg)*/
#define MPFROMSH2CH(s, uch1, uch2) ((MPARAM)MAKELONG(s, MAKESHORT(uch1, uch2)))
```

Macros for extracting data from a [MPARAM](#) variable are shown below:

```
/* Used to get any pointer type: */
#define PVOIDFROMMP(mp) ((VOID*)(mp))

/* Used to get a window handle: */
```

```

#define HWNDFROMMP(mp)      ((HWND)(mp))

/* Used to get CHAR, UCHAR, or BYTE: */
#define CHAR1FROMMP(mp)     ((UCHAR)(mp))
#define CHAR2FROMMP(mp)     ((UCHAR)((ULONG)mp >> 8))
#define CHAR3FROMMP(mp)     ((UCHAR)((ULONG)mp >> 16))
#define CHAR4FROMMP(mp)     ((UCHAR)((ULONG)mp >> 24))

/* Used to get a LONG, ULONG, or BOOL: */
#define LONGFROMMP(mp)      ((ULONG)(mp))

```

Macros for packing data into a [MRESULT](#) variable are shown below:

```

/* Used to pass any pointer type: */
#define MRFROMP(p)           ((MRESULT)(VOID*)(p))

/* Used to pass a LONG, ULONG, or BOOL: */
#define MRFROMLONG(l)        ((MRESULT)(ULONG)(l))

/* Used to pass two SHORTs or USHORTs: */
#define MRFROM2SHORT(s1, s2) ((MRESULT)MAKELONG(s1, s2))

```

Macros for extracting data from a [MRESULT](#) variable are shown below:

```

/* Used to get any pointer type: */
#define PVOIDFROMMR(mr)      ((VOID*)(mr))

/* Used to get a LONG, ULONG, or BOOL: */
#define LONGFROMMR(mr)       ((ULONG)(mr))

```

The following macros are for use with [DDESTRUCT](#) and [DDEINIT](#) structures are shown below:

```

/* Used to return a PSZ pointing to the DDE item name: */
#define DDES_PSZITEMNAME(pddes) \
    (((PSZ)pddes) + ((PDDESTRUCT)pddes)->offsItemName)

/* Used to return a PBYTE pointing to the DDE data: */
#define DDES_PABDATA(pddes) \
    (((PBYTE)pddes) + ((PDDESTRUCT)pddes)->offabData)

/* Used to convert a selector to a PDDESTRUCT: */
#define SELTOPDDES(sel)       ((PDDESTRUCT)MAKEP(sel, 0))

/* Used to PDDESTRUCT to a selector for freeing / reallocating: */
#define PDDESTOSEL(pddes)     (SELECTOROF(pddes))

/* Used to PDDEINIT to a selector for freeing: */
#define PDDEITOSEL(pddei)     (SELECTOROF(pddei))

```

Addressing Elements in Arrays

Constants defining array elements are given values that are zero-based in C; that is, the numbering of the array elements starts at zero, not one.

For example, in the [DevQueryCaps](#) function, the sixth element of the *alArray* parameter is CAPS_HEIGHT, which is equated to 5.

Count parameters related to such arrays always mean the actual number of elements available; therefore, again using the [DevQueryCaps](#) function as an example, if all elements up to and including CAPS_HEIGHT are provided for, *lCount* could be set to (CAPS_HEIGHT+1).

In functions for which the starting array element can be specified, this is always zero-based, and so the C element number constants can be

used directly. For example, to start with the CAPS_HEIGHT element, the */Start* parameter can be set to CAPS_HEIGHT.

Implicit Pointer Data Types

A data type name beginning with "P" (for example, PERRORCODE) is likely to be a pointer to another data type (in this instance, ERRORCODE).

In the data type summary, no explicit "typedefs" are shown for pointers; therefore, if no data type definition can be found in the summary for a data type name "Pxxxxxx", it represents a pointer to the data type "xxxxxx", for which a definition should be found in the reference.

The implicit type definition needed for such a pointer "Pxxxxxx" is:

```
typedef xxxxxx *Pxxxxxx;
```

Such definitions are provided in the header files.

Storage Mapping of Data Types

The storage mapping of the data types is dependent on the machine architecture. To be portable, applications must access the data types using the definitions supplied for the environment in which they will execute.

Double-Byte Character Set (DBCS)

Throughout this publication, you will see references to specific value for character strings. The values are for single-byte character set (SBCS). If you use the double-byte character set (DBCS), note that one DBCS character equals two SBCS characters.

Programming Considerations

This section provides information you need to consider before you begin programming with Presentation Manager functions.

Stack Size

Existing 16-bit applications (small and tiny models) must have a 4KB stack available when they enter system calls; otherwise, the stack can overflow into the data area.

Presentation Manager

The Presentation Manager component of the OS/2 operating system is based on the IBM Systems Application Architecture (SAA) Common

Programming Interface-a an architecture for the design and development of applications.

The Presentation Manager component implements the Common User Access (CUA) interface, which you can use to attain consistency in the appearance and behavior of your applications.

C++ Considerations

This section contains several topics you should take into consideration if you are using C++ to develop applications.

A Few Words on Typedefs

The OS/2 header files can be used with either C or C++ compilers. If `__cplusplus` has been defined, the header files will produce code that is compatible with C++. This is done since several of the typedefs have been changed to support C++. For example, many items that are unsigned char in the "C header files" are char when compiled with `__cplusplus`. For instance,

```
typedef unsigned char BYTE;
```

has changed to

```
typedef char BYTE;
```

The existing samples that are included in the IBM Developer's Toolkit for OS/2 Warp Version 3 can be compiled with either C or C++.

Note: Prior versions of the IBM Developer's Toolkit for OS/2 Warp Version 3 provided two sets of header files: one set for use with C compilers, another set for use with C++ compilers. The same set of header files are now used by either compiler.

PCSZ Data Type

If a function takes as a parameter a string that is not changed by the function, the string parameter can be declared as a "const" string, or a [PCSZ](#). [PCSZ](#) is defined in the header files as a "const" pointer to a NULL-delimited string.

The "const" means that the function will not change the contents of the string. The use of the "const" keyword is not specific to C++, many C compilers support it as well. However, the use of [PCSZ](#) allows for better optimization by the compiler and is more semantically compatible with C++.

The [PCSZ](#) data type is defined in addition to the [PSZ](#) data type. Existing code that calls functions that use [PSZ](#) will continue to work correctly, though they may cause warning or error messages when compiled.

LINK386

The C++ compiler will provide a dynamic link library which is be used by LINK386, or other OS/2 linker, when generating error messages.

This DLL will convert a compiler generated mangled name into the function prototype. If the DLL is not present, an error message will be displayed and LINK386 will display the compiler-generated mangled name in error messages.

Device Functions

This section describes functions that an application would use to query or access devices.

DevCloseDC

DevCloseDC - Syntax

This function closes a device context.

```
#define INCL_DEV /* Or use INCL_PM, Also in COMMON section */
#include <os2.h>

HDC     hdc; /* Device-context handle. */
HMF     hmf; /* Error indicator metafile handle (for a metafile device context) */

hmf = DevCloseDC(hdc);
```

DevCloseDC Parameter - hdc

hdc (**HDC**) - input
Device-context handle.

DevCloseDC Return Value - hmf

hmf (**HMF**) - returns
Error indicator metafile handle (for a metafile device context)

DEV_ERROR	Error occurred.
DEV_OK	Device closed, but not a metafile device context.
Other	Device closed, a metafile device context whose metafile handle is returned.

DevCloseDC - Parameters

hdc ([HDC](#)) - input
Device-context handle.

hmf ([HMF](#)) - returns
Error indicator metafile handle (for a metafile device context)

DEV_ERROR	Error occurred.
DEV_OK	Device closed, but not a metafile device context.
Other	Device closed, a metafile device context whose metafile handle is returned.

DevCloseDC - Remarks

If the device context is currently associated with a presentation space, or if it is created with the [WinOpenWindowDC](#) call (that is, it is a screen device context), an error is raised, and the device context is not closed.

If the device context being closed is a memory device context that has a bit map currently selected into it (see "GpiSetBitmap" in the *Presentation Manager Programming Reference*) the bit map is automatically deselected before the device context is closed.

Any clip region currently in use for this device context is deleted.

DevCloseDC - Errors

Possible returns from [WinGetLastError](#)

PMERR_NOT_CREATED_BY_DEVOPENDC (0x20DC)
An attempt has been made to destroy a device context using DevCloseDC that was not created using [DevOpenDC](#).

PMERR_DC_IS_ASSOCIATED (0x2017)
An attempt was made to associate a presentation space with a device context that was already associated or to destroy a device context that was associated.

PMERR_INV_HDC (0x207C)
An invalid device-context handle or (micro presentation space) presentation-space handle was specified.

DevCloseDC - Related Functions

Prerequisite Functions

- [DevOpenDC](#)

Related Functions

- [WinOpenWindowDC](#)

DevCloseDC - Example Code

This example calls DevCloseDC to close a device context based on the handle returned from DevOpenDC.

```
#define INCL_DEV                      /* Device Function definitions */
#include <os2.h>

HDC hdc;                             /* Device-context handle */
HMF hmf;                             /* error code (or metafile handle if
                                     metafile device context) */

/* close the device context associated with handle hdc */
hmf = DevCloseDC(hdc);
```

DevCloseDC - Topics

Select an item:

[Syntax](#)
[Parameters](#)
[Returns](#)
[Errors](#)
[Remarks](#)
[Example Code](#)
[Related Functions](#)
[Glossary](#)

DevEscape

DevEscape - Syntax

This function allows applications to access facilities of a device not otherwise available through the API. Escapes are, in general, sent to the presentation driver and must be understood by it.

```
#define INCL_DEV /* Or use INCL_PM, */
#include <os2.h>

HDC     hdc;          /* Device-context handle. */
LONG    lCode;        /* Escape code. */
LONG    lInCount;     /* Input data count. */
PBYTE   pbInData;     /* The input data required for this escape. */
PLONG    plOutCount;  /* Output data count. */
PBYTE   pbOutData;    /* Output data. */
LONG    lResult;      /* Implementation error indicator: */

lResult = DevEscape(hdc, lCode, lInCount,
```

```
pbInData, plOutCount, pbOutData);
```

DevEscape Parameter - hdc

hdc ([HDC](#)) - input
Device-context handle.

DevEscape Parameter - ICode

ICode ([LONG](#)) - input
Escape code.

If the device context is of type OD_QUEUED with a PM_Q_STD spool file, some escapes are sent to the presentation driver and others are recorded in the spool file (depending on the escape code). If the device context is of type OD_METAFILE, all escapes are metafiled. If the device context is of any type other than OD_QUEUED (with a PM_Q_STD spool file) or OD_METAFILE, all escapes are sent to the presentation driver.

The description for each standard escape specifies which of these categories the escape falls into.

Devices can define additional escape functions using user *ICode* values, that have the following ranges:

32 768 through 40 959	Not metafiled and not recorded (sent to presentation driver for PM_Q_STD)
40 960 through 49 151	Metafiled only (sent to presentation driver for PM_Q_STD)
49 152 through 57 343	Metafiled and recorded (not sent to presentation driver) for PM_Q_STD
57 344 through 65 535	Recorded only (not sent to presentation driver for PM_Q_STD).

The following escapes are defined:

DEVESC_QUERYESCSUPPORT
DEVESC_GETSCALINGFACTOR
DEVESC_STARTDOC
DEVESC_ENDDOC
DEVESC_ABORTDOC
DEVESC_NEWFRAME
DEVESC_RAWDATA
DEVESC_QUERYVIOCELLSIZES
DEVESC_SETMODE

DevEscape Parameter - IInCount

lInCount (**LONG**) - input
Input data count.

Number of bytes of data in the *pbInData* buffer.

DevEscape Parameter - pbInData

pbInData (**PBYTE**) - input
The input data required for this escape.

DevEscape Parameter - plOutCount

plOutCount (**PLONG**) - in/out
Output data count.

plOutCount is the number of bytes of data in the *pbOutData* buffer.

If data is returned in *pbOutData* , *plOutCount* is updated to the number of bytes of data returned.

DevEscape Parameter - pbOutData

pbOutData (**PBYTE**) - output
Output data.

pbOutData is a buffer that receives the output from this escape. If *plOutCount* is null, no data is returned.

DevEscape Return Value - IResult

IResult (**LONG**) - returns
Implementation error indicator:

DEVESC_ERROR	Error
DEVESC_NOTIMPLEMENTED	Escape not implemented for specified code
DEV_OK	OK.

DevEscape - Parameters

hdc ([HDC](#)) - input
Device-context handle.

ICode ([LONG](#)) - input
Escape code.

If the device context is of type OD_QUEUED with a PM_Q_STD spool file, some escapes are sent to the presentation driver and others are recorded in the spool file (depending on the escape code). If the device context is of type OD_METAFILE, all escapes are metafiled. If the device context is of any type other than OD_QUEUED (with a PM_Q_STD spool file) or OD_METAFILE, all escapes are sent to the presentation driver.

The description for each standard escape specifies which of these categories the escape falls into.

Devices can define additional escape functions using user *ICode* values, that have the following ranges:

32 768 through 40 959	Not metafiled and not recorded (sent to presentation driver for PM_Q_STD)
40 960 through 49 151	Metafiled only (sent to presentation driver for PM_Q_STD)
49 152 through 57 343	Metafiled and recorded (not sent to presentation driver) for PM_Q_STD
57 344 through 65 535	Recorded only (not sent to presentation driver for PM_Q_STD).

The following escapes are defined:

DEVESC_QUERYESCSUPPORT
DEVESC_GETSCALINGFACTOR
DEVESC_STARTDOC
DEVESC_ENDDOC
DEVESC_ABORTDOC
DEVESC_NEWFRAME
DEVESC_RAWDATA
DEVESC_QUERYVIOCELLSIZES
DEVESC_SETMODE

lInCount ([LONG](#)) - input
Input data count.

Number of bytes of data in the *pbInData* buffer.

pbInData ([PBYTE](#)) - input
The input data required for this escape.

pOutCount ([PLONG](#)) - in/out
Output data count.

pOutCount is the number of bytes of data in the *pbOutData* buffer.

If data is returned in *pbOutData*, *pOutCount* is updated to the number of bytes of data returned.

pbOutData ([PBYTE](#)) - output
Output data.

pbOutData is a buffer that receives the output from this escape. If *pOutCount* is null, no data is returned.

IResult (LONG) - returns
Implementation error indicator:

DEVESC_ERROR	Error
DEVESC_NOTIMPLEMENTED	Escape not implemented for specified code
DEV_OK	OK.

DevEscape - Remarks

The data fields for standard escapes are:

DEVESC_QUERYESCSUPPORT
Queries whether a particular escape is implemented by the presentation driver. The return value gives the result.

This escape is not metafiled or recorded.

<i>lInCount</i>	Number of bytes pointed to by <i>pbInData</i> .
<i>pbInData</i>	The buffer contains an escape code value specifying the escape function to be checked.
<i>plOutCount</i>	Not used; can be set to 0.
<i>pbOutData</i>	Not used; can be set to null.

DEVESC_GETSCALINGFACTOR
Returns the scaling factors for the x and y axes of a printing device. For each scaling factor, an exponent of two is put in *pbOutData*. Thus, the value 3 is used if the scaling factor is 8.

Scaling factors are used by devices that cannot support graphics at the same resolution as the device resolution.

This escape is not metafiled or recorded.

<i>lInCount</i>	Not used; can be set to 0.
<i>pbInData</i>	Not used; can be set to null.
<i>plOutCount</i>	The number of bytes of data pointed to by <i>pbOutData</i> . On return, this is updated to the number of bytes returned.
<i>pbOutData</i>	The address of a SFACTORS structure, which on return contains the scaling factors for the x and y axes.

DEVESC_STARTDOC
Indicates that a new print job is starting. All subsequent output to the device context is spooled under the same job identifier until a DEVESC_ENDDOC occurs.

GpiAssociate must be issued to associate the presentation space with the device context before issuing this escape.

This escape is metafiled but not recorded.

<i>lInCount</i>	Number of bytes pointed to by <i>pbInData</i> .
<i>pbInData</i>	The buffer contains a null-terminated string, specifying the name of the document.
<i>plOutCount</i>	Not used; can be set to 0.
<i>pbOutData</i>	Not used; can be set to null.

DEVESC_ENDDOC
Ends a print job started by DEVESC_STARTDOC.

This escape is metafiled but not recorded.

<i>lInCount</i>	Not used; can be set to 0.
<i>pbInData</i>	Not used; can be set to null.
<i>plOutCount</i>	Set equal to 2.
<i>pbOutData</i>	The buffer contains a USHORT specifying the job identifier if a spooler print job is created.

DEVESC_ABORTDOC
Aborts the current job, erasing everything the application has written to the device since the last DEVESC_STARTDOC, including the DEVESC_STARTDOC.

This escape is metafiled but not recorded.

<i>lInCount</i>	Not used; can be set to 0
<i>pbInData</i>	Not used; can be set to null
<i>pOutCount</i>	Not used; can be set to 0
<i>pbOutData</i>	Not used; can be set to null.

DEVESC_NEWFRAME

Signals when an application has finished writing to a page and wants to start a new page. It is similar to GpiErase processing for a screen device context, and causes a reset of the attributes. This escape is used with a printer device to advance to a new page.

This escape is metafiled and recorded.

<i>lInCount</i>	Not used; can be set to 0
<i>pbInData</i>	Not used; can be set to null
<i>pOutCount</i>	Not used; can be set to 0
<i>pbOutData</i>	Not used; can be set to null.

DEVESC_RAWDATA

Allows an application to send data directly to a presentation driver. For example, in the case of a printer driver, this could be a printer data stream.

If DEVESC_RAWDATA is mixed with other data (such as GPI data) being sent to the same page of a device context, the results are unpredictable and depend upon the action taken by the presentation driver. For example, a presentation driver might ignore GPI data if DEVESC_RAWDATA is mixed with it on the same page. In general, DEVESC_RAWDATA should be sent either to a separate page (using the DEVESC_NEWFRAME escape to obtain a new page) or to a separate document (using the DEVESC_STARTDOC and DEVESC_ENDDOC escapes to create a new document).

This escape is metafiled and recorded.

<i>lInCount</i>	Number of bytes pointed to by <i>pbInData</i>
<i>pbInData</i>	Pointer to the raw data
<i>pOutCount</i>	Not used; can be set to 0
<i>pbOutData</i>	Not used; can be set to null.

DEVESC_QUERYVIOCELLSIZES

Returns the VIO cell sizes supported by the presentation driver.

This escape is not metafiled or recorded.

<i>lInCount</i>	Not used; can be set to 0
<i>pbInData</i>	Not used; can be set to null.
<i>pOutCount</i>	The number of bytes of data pointed to by <i>pbOutData</i> . It must be an even multiple of the size in bytes of the LONG data type. On return, this is updated to the number of bytes returned.
<i>pbOutData</i>	<p>The address of a buffer, which on return contains a VIO_SIZE_COUNT structure, immediately followed by <i>count</i> copies of a VIO_FONT_CELL_SIZE structure.</p> <p>If <i>pOutCount</i> is less than the size of a LONG data type, <i>pOutCount</i> is updated to zero, and nothing is returned in the buffer pointed to by <i>pbOutData</i>.</p> <p>If <i>pOutCount</i> is equal to the size of a LONG data type, <i>pbOutData</i> returns the number of VIO cell sizes that can be returned by this escape. The buffer pointed to by <i>pbOutData</i> is updated so that <i>maxcount</i> is the number of VIO cell sizes that can be returned.</p> <p>If <i>pOutCount</i> is greater than the size of a LONG data type, <i>pbOutData</i> returns the VIO cell sizes that are supported. The buffer pointed to by <i>pbOutData</i> is updated so that:</p> <ul style="list-style-type: none">• <i>maxcount</i> is the number of VIO cell sizes that can be returned• <i>count</i> is the number of VIO cell sizes returned (may be zero if <i>pOutCount</i> is equal to twice the size of a LONG data type)• <i>count</i> copies of a VIO_FONT_CELL_SIZE structure are returned.

DEVESC_SETMODE

Sets the printer into a particular mode. It is optional for printer drivers to support this escape, but those that do support it need to be aware of the code page of any built-in fonts. For example, if only code page 437 is built in, it is used if 437 is requested by DEVESC_SETMODE; however, if code page 865 is requested, a suitable code page/font could be downloaded.

This escape is metafiled and recorded.

lInCount
pbInData
plOutCount
pbOutData

Number of bytes pointed to by *pbInData*
Buffer contains an [ESCSETMODE](#) structure
Not used; can be set to 0
Not used; can be set to null.

DevEscape - Errors

Possible returns from [WinGetLastError](#)

PMERR_INV_ESC_CODE (0x206D)

An invalid escape code was used in a call to DevEscape.

PMERR_INV_HDC (0x207C)

An invalid device-context handle or (micro presentation space) presentation-space handle was specified.

PMERR_INV_LENGTH_OR_COUNT (0x2092)

An invalid length or count parameter was specified.

PMERR_ESC_CODE_NOT_SUPPORTED (0x202B)

The code specified with DevEscape is not supported by the target device driver.

PMERR_INV_ESCAPE_DATA (0x206E)

An invalid data parameter was specified with DevEscape.

DevEscape - Graphic Elements and Orders

DevEscape functions generate orders only when metafileing.

Order: GEESCP

DevEscape - Example Code

This example uses DevEscape to access facilities of a device that would otherwise be unavailable through the normal Device API set. Here,

a new page in a print job is started.

```
#define INCL_DEV          /* Device Function definitions */
#include <os2.h>

LONG  lResult;           /* Error code or not implemented
                           warning code */
HDC   hdc;               /* Device-context handle */
LONG  plOutCount;        /* length of output buffer(input),
                           number of bytes returned(output) */
PBYTE pbOutData;         /* output buffer */

/* for the NEWFRAME, input and output buffers are not used,
   so set the buffer lengths to zero(0) and set the buffers to
   NULL */
plOutCount = 0;
pbOutData = NULL;

lResult = DevEscape(hdc, DEVEscape_NEWFRAME, 0L, NULL, &plOutCount,
                    pbOutData);
```

DevOpenDC

DevOpenDC - Syntax

This function creates a device context.

```
#define INCL_DEV /* Or use INCL_PM, Also in COMMON section */
#include <os2.h>

HAB      hab;           /* Anchor-block handle. */
LONG     lType;          /* Type of device context: */
PSZ      pszToken;       /* Device-information token. */
LONG     lCount;         /* Number of items. */
PDEVOPENDATA pdopData;   /* Open-device-context data area. */
HDC      hdcComp;        /* Compatible-device-context handle. */
HDC      hdc;            /* Device-context handle: */

hdc = DevOpenDC(hab, lType, pszToken, lCount,
                pdopData, hdcComp);
```

DevOpenDC Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

DevOpenDC Parameter - IType

IType ([LONG](#)) - input
Type of device context:

- OD_QUEUED**
A device, such as a printer or plotter, for which output is to be queued.
Certain restrictions apply for this device type;
- OD_DIRECT**
A device, such as a printer or plotter, for which output is not to be queued.
- OD_INFO**
A device, such as a printer or plotter, but the device context is used only to retrieve information (for example, font metrics). Drawing can be performed to a presentation space associated with such a device context, but no output medium is updated.
- OD_METAFILE**
The device context is used to write a metafile. The presentation page defines the area of interest within the picture in the metafile. See [OD_METAFILE_NOQUERY](#).
Certain restrictions apply for this device type;
- OD_METAFILE_NOQUERY**
The device context is used to write a metafile.
Functionally, this device type is the same as [OD_METAFILE](#), except that querying of attributes is not allowed with a presentation space while it is associated with an [OD_METAFILE_NOQUERY](#) device context. If querying of attributes is not required, [OD_METAFILE_NOQUERY](#) should be used in preference to [OD_METAFILE](#), since it gives improved performance.
Certain restrictions apply for this device type;
- OD_MEMORY**
A device context that is used to contain a bit map. The *hdcComp* parameter identifies a device with which the memory device context is to be compatible.
-

DevOpenDC Parameter - pszToken

pszToken ([PSZ](#)) - input
Device-information token.

This identifies the device information, held in the initialization file. This information is the same as that which may be pointed to by

pdopData; any information that is obtained from *pdopData* overrides the information obtained by using this parameter.

If *pszToken* is specified as "", no device information is taken from the initialization file.

OS/2 behaves as if "" is specified, but it allows any string.

DevOpenDC Parameter - ICount

ICount (**LONG**) - input
Number of items.

This is the number of items present in the *pdopData* parameter. This can be less than the full list if omitted items are irrelevant, or are supplied from *pszToken* or elsewhere.

DevOpenDC Parameter - pdopData

pdopData (**PDEVOPENDATA**) - input
Open-device-context data area.

DevOpenDC Parameter - hdcComp

hdcComp (**HDC**) - input
Compatible-device-context handle.

When */Type* is OD_MEMORY, this parameter is a handle to a device context compatible with bit maps that are to be used with this device context.

If *hdcComp* is NULLHANDLE, compatibility with the screen is assumed.

DevOpenDC Return Value - hdc

hdc (**HDC**) - returns
Device-context handle:

DEV_ERROR

Error

<>0

Device-context handle.

DevOpenDC - Parameters

hab (**HAB**) - input
Anchor-block handle.

IType (**LONG**) - input
Type of device context:

- OD_QUEUED**
A device, such as a printer or plotter, for which output is to be queued.
Certain restrictions apply for this device type;
- OD_DIRECT**
A device, such as a printer or plotter, for which output is not to be queued.
- OD_INFO**
A device, such as a printer or plotter, but the device context is used only to retrieve information (for example, font metrics). Drawing can be performed to a presentation space associated with such a device context, but no output medium is updated.
- OD_METAFILE**
The device context is used to write a metafile. The presentation page defines the area of interest within the picture in the metafile. See **OD_METAFILE_NOQUERY**.
Certain restrictions apply for this device type;
- OD_METAFILE_NOQUERY**
The device context is used to write a metafile.
Functionally, this device type is the same as **OD_METAFILE**, except that querying of attributes is not allowed with a presentation space while it is associated with an **OD_METAFILE_NOQUERY** device context. If querying of attributes is not required, **OD_METAFILE_NOQUERY** should be used in preference to **OD_METAFILE**, since it gives improved performance.
Certain restrictions apply for this device type;
- OD_MEMORY**
A device context that is used to contain a bit map. The *hdcComp* parameter identifies a device with which the memory device context is to be compatible.

pszToken (**PSZ**) - input
Device-information token.

This identifies the device information, held in the initialization file. This information is the same as that which may be pointed to by *pdopData*; any information that is obtained from *pdopData* overrides the information obtained by using this parameter.

If *pszToken* is specified as **""**, no device information is taken from the initialization file.

OS/2 behaves as if **""** is specified, but it allows any string.

ICount (**LONG**) - input
Number of items.

This is the number of items present in the *pdopData* parameter. This can be less than the full list if omitted items are irrelevant, or are supplied from *pszToken* or elsewhere.

pdopData (**PDEVOPENDATA**) - input
Open-device-context data area.

hdcComp (**HDC**) - input
Compatible-device-context handle.

When *IType* is **OD_MEMORY**, this parameter is a handle to a device context compatible with bit maps that are to be used with this device context.

If *hdcComp* is **NULLHANDLE**, compatibility with the screen is assumed.

hdc (**HDC**) - returns
Device-context handle:

DEV_ERROR

<>0 Error
Device-context handle.

DevOpenDC - Remarks

A device context is a means of writing to a particular device. Before using GPI functions to cause output to be directed to the device context, the GpiAssociate function call must be issued (or the GPIA_ASSOC option specified on GpiCreatePS).

DevOpenDC cannot be used to open a device context for a screen window; use [WinOpenWindowDC](#) instead.

The device context is owned by the process from which DevOpenDC is issued. It cannot be accessed directly from any other process. If it still exists when the process terminates, it is automatically deleted by the system. When using a device context type of OD_METAFILE_NOQUERY the querying of attributes is not allowed. To improve performance of this type of metafile no error checking is performed to ensure that such API calls are not attempted. Query calls are accepted but the results returned are undefined.

This function requires the existence of a message queue.

DevOpenDC - Errors

Possible returns from [WinGetLastError](#)

PMERR_INV_DC_TYPE (0x2060)

An invalid type parameter was specified with DevOpenDC, or a function was issued that is invalid for a OD_METAFILE_NOQUERY device context.

PMERR_INV_LENGTH_OR_COUNT (0x2092)

An invalid length or count parameter was specified.

PMERR_INV_DC_DATA (0x205F)

An invalid data parameter was specified with DevOpenDC.

PMERR_INV_HDC (0x207C)

An invalid device-context handle or (micro presentation space) presentation-space handle was specified.

PMERR_INV_DRIVER_NAME (0x2067)

A driver name was specified which has not been installed.

PMERR_INV_LOGICAL_ADDRESS (0x2097)

An invalid device logical address was specified.

DevOpenDC - Example Code

This example calls DevOpenDC to create a memory device context with screen compatibility and then associates that context with a newly created presentation space.

```
#define INCL_DEV                /* Device Function definitions */
#define INCL_GPICONTROL        /* GPI control Functions */
#include <os2.h>

HDC   hdc;                /* Device-context handle */
HAB   hab;                /* Anchor-block handle */
/* context data structure */
DEVOPENSTRUC dop = {NULL, "DISPLAY", NULL, NULL, NULL, NULL,
                    NULL, NULL, NULL};
HPS   hps;                /* presentation-space handle */
SIZEL sizl={0, 0};        /* use same page size as device */

/* create memory device context */
hdc = DevOpenDC(hab, OD_MEMORY, "", 5L, (PDEVOPENDATA)&dop, NULLHANDLE);

/* create a presentation space associated with the context */
hps = GpiCreatePS(hab, hdc, &sizl, GPIA_ASSOC | PU_PELS);
```

DevPostDeviceModes

DevPostDeviceModes - Syntax

This function returns, and optionally sets job properties.

```
#define INCL_DEV /* Or use INCL_PM, */
#include <os2.h>

HAB   hab;                /* Anchor-block handle. */
PDRIVDATA pdrvDriverData; /* Driver data. */
PSZ    pszDriverName;     /* Device-driver name. A string containing the name of the presentation driver;
```

```

PSZ          pszDeviceName;    /* Device-type name. */
PSZ          pszName;          /* Device name. */
ULONG        flOptions;        /* Dialog options. */
LONG         lDriverCount;     /* Size/error indicator. */

lDriverCount = DevPostDeviceModes(hab, pdrvDriverData,
                                   pszDriverName, pszDeviceName,
                                   pszName, flOptions);

```

DevPostDeviceModes Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

DevPostDeviceModes Parameter - pdrvDriverData

pdrvDriverData ([PDRIVDATA](#)) - in/out
Driver data.

A data area that, on return, contains device data defined by the presentation driver. If the pointer to the area is NULL, this function returns the required size of the data area.

The format of the data is the same as that which occurs within the [DEVOPENSTRUC](#) structure, passed on the *pdrvData* parameter of [DevOpenDC](#).

DevPostDeviceModes Parameter - pszDriverName

pszDriverName ([PSZ](#)) - input
Device-driver name. A string containing the name of the presentation driver; for example, "LASERJET".

DevPostDeviceModes Parameter - pszDeviceName

pszDeviceName ([PSZ](#)) - input
Device-type name.

Null-terminated string in a 32-byte field, identifying the device type; for example, "HP LaserJet IID" (model number). Valid names are defined by device drivers.

Note: This parameter always overrides the data in the *szDeviceName* field of the [DRIVDATA](#) structure, passed in the *pdrvDriverData* parameter.

DevPostDeviceModes Parameter - pszName

pszName ([PSZ](#)) - input
Device name.

A name that identifies the device; for example, "PRINTER1".

DevPostDeviceModes Parameter - flOptions

flOptions ([ULONG](#)) - input
Dialog options.

Options that control whether a dialog is displayed.

DPDM_POSTJOBPROP

This function allows the user to set properties for the print job by displaying a dialog and returning the updated job properties. Examples of job properties are paper size, paper orientation, and single-sided or duplex.

The printer is configured in the shell using a dialog provided by the presentation driver. The configuration describes the actual printer setup such as number of paper bins, available paper sizes, and any installed hardware fonts.

Before the job properties dialog is displayed the presentation driver merges any changes in the printer configuration with the data passed in the *pdrvDriverData* parameter. This allows, for example new paper sizes to be added into the job properties dialog. The parameter *pszName* can be specified as NULL although this is not recommended because the presentation driver cannot easily find the printer configuration to merge.

It is the responsibility of the application to retrieve and store job properties. An application can choose to store job properties either on a per document or per application basis. The job properties can then be passed into [DevOpenDC](#). Initial (default) job properties can be retrieved using DPDM_QUERYJOBPROP option.

The application cannot tell if the user modified the job properties or just cancelled the dialog. Hence the job properties returned in the *pdrvDriverData* parameter must always be stored.

The shell allows users to specify default job properties for a printer. The spooler API [SplQueryQueue](#) can be used to retrieve these defaults. The spooler automatically adds the default job properties for a printer to any jobs that are submitted without job properties.

DPDM_QUERYJOBPROP

Do not display a dialog. Return the default job properties. These defaults are derived from the defaults for the chosen device; for example, "HP Laserjet IID" and the printer setup specified via the shell printer driver configuration dialog.

DevPostDeviceModes Return Value - IDriverCount

IDriverCount ([LONG](#)) - returns
Size/error indicator.

Value depends on what was passed as the pointer to *pdrvDriverData*. If NULL was passed, the following values are possible:

DPDM_ERROR
DPDM_NONE
>0

Error
No settable options
Size in bytes required for *pdrvDriverData*.

If any other value was passed, the following values are possible:

DPDM_ERROR	Error
DPDM_NONE	No settable options
DEV_OK	OK.

DevPostDeviceModes - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

pdrvDriverData ([PDRIVDATA](#)) - in/out
Driver data.

A data area that, on return, contains device data defined by the presentation driver. If the pointer to the area is NULL, this function returns the required size of the data area.

The format of the data is the same as that which occurs within the [DEVOPENSTRUC](#) structure, passed on the *pdrvData* parameter of [DevOpenDC](#).

pszDriverName ([PSZ](#)) - input
Device-driver name. A string containing the name of the presentation driver; for example, "LASERJET".

pszDeviceName ([PSZ](#)) - input
Device-type name.

Null-terminated string in a 32-byte field, identifying the device type; for example, "HP LaserJet IID" (model number). Valid names are defined by device drivers.

Note: This parameter always overrides the data in the *szDeviceName* field of the [DRIVDATA](#) structure, passed in the *pdrvDriverData* parameter.

pszName ([PSZ](#)) - input
Device name.

A name that identifies the device; for example, "PRINTER1".

flOptions ([ULONG](#)) - input
Dialog options.

Options that control whether a dialog is displayed.

DPDM_POSTJOBPROP

This function allows the user to set properties for the print job by displaying a dialog and returning the updated job properties. Examples of job properties are paper size, paper orientation, and single-sided or duplex.

The printer is configured in the shell using a dialog provided by the presentation driver. The configuration describes the actual printer setup such as number of paper bins, available paper sizes, and any installed hardware fonts.

Before the job properties dialog is displayed the presentation driver merges any changes in the printer configuration with the data passed in the *pdrvDriverData* parameter. This allows, for example new paper sizes to be added into the job properties dialog. The parameter *pszName* can be specified as NULL although this is not recommended because the presentation driver cannot easily find the printer configuration to merge.

It is the responsibility of the application to retrieve and store job properties. An application can choose to store job properties either on a per document or per application basis. The job properties can then be passed into [DevOpenDC](#). Initial (default) job properties can be retrieved using DPDM_QUERYJOBPROP option.

The application cannot tell if the user modified the job properties or just cancelled the dialog. Hence the job properties returned in the *pdrvDriverData* parameter must always be stored.

The shell allows users to specify default job properties for a printer. The spooler API [SpiQueryQueue](#) can be used to retrieve these defaults. The spooler automatically adds the default job properties for a printer to any jobs that are submitted without job properties.

DPDM_QUERYJOBPROP

Do not display a dialog. Return the default job properties. These defaults are derived from the defaults for the chosen device; for example, "HP Laserjet IID" and the printer setup specified via the shell printer driver configuration dialog.

IDriverCount ([LONG](#)) - returns
Size/error indicator.

Value depends on what was passed as the pointer to *pdrivDriverData*. If NULL was passed, the following values are possible:

DPDM_ERROR	Error
DPDM_NONE	No settable options
>0	Size in bytes required for <i>pdrivDriverData</i> .

If any other value was passed, the following values are possible:

DPDM_ERROR	Error
DPDM_NONE	No settable options
DEV_OK	OK.

DevPostDeviceModes - Remarks

An application can first call this function with a NULL data pointer to find out how much storage is needed for the data area. Having allocated the storage, the application can then make the call a second time for the data to be entered. The returned data can then be passed in [DevOpenDC](#) as *pdrivDriverData* within the *pdpData* parameter.

Calling this function requires the existence of a message queue.

Use [SplEnumDevice](#) or [SplEnumPrinter](#) with *//Type* set to SPL_PR_DIRECT_DEVICE or SPL_PR_QUEUED_DEVICE to get a list of all the devices.

To get information about a specific device use [SplQueryDevice](#).

DevPostDeviceModes - Errors

Possible returns from [WinGetLastError](#)

PMERR_INV_DRIVER_DATA (0x2066)
Invalid driver data was specified.

PMERR_DRIVER_NOT_FOUND (0x2026)
The device driver specified with DevPostDeviceModes was not found.

PMERR_INV_DEVICE_NAME (0x2061)
An invalid devicename parameter was specified with DevPostDeviceModes.

PMERR_INV_LOGICAL_ADDRESS (0x2097)
An invalid device logical address was specified.

DevPostDeviceModes - Example Code

This example shows how to call DevPostDeviceModes and allocate a new buffer, if necessary, for the larger job properties (DRIVDATA structure).

```
#define INCL_DEV
#define INCL_DOS
#include <os2.h>
#include <memory.h>

{
    ULONG          devrc=FALSE;
    HAB            hab;
    PSZ            pszPrinter;
    HDC            hdc=NULL;
    PDRIVDATA      pOldDrvData;
    PDRIVDATA      pNewDrvData=NULL;
    PDEVOPENSTRUC dops;
    LONG           buflen;

    /* check size of buffer required for job properties */
    buflen = DevPostDeviceModes( hab,
                                NULL,
                                dops->pszDriverName,
                                dops->pdriv->szDeviceName,
                                pszPrinter,
                                DPDM_POSTJOBPROP
                                );

    /* return error to caller */
    if (buflen<=0)
        return(buflen);

    /* allocate some memory for larger job properties and */
    /* return error to caller */

    if (buflen != dops->pdriv->cb)
    {
        if (DosAllocMem((PVOID)&pNewDrvData,buflen,FALLOC))
            return(DPDM_ERROR);
    }

    /* copy over old data so driver can use old job */
    /* properties as base for job properties dialog */
    pOldDrvData = dops->pdriv;
    dops->pdriv = pNewDrvData;
    memcpy( (PSZ)pNewDrvData, (PSZ)pOldDrvData, pOldDrvData->cb );

    /* display job properties dialog and get updated */
    /* job properties from driver */

    devrc = DevPostDeviceModes( hab,
                                dops->pdriv,
                                dops->pszDriverName,
                                dops->pdriv->szDeviceName,
                                pszPrinter,
                                DPDM_POSTJOBPROP
                                );

    return(devrc);
}
```

DevQueryCaps

DevQueryCaps - Syntax

This function queries the device characteristics.

```
#define INCL_DEV /* Or use INCL_PM, Also in COMMON section */
#include <os2.h>

HDC      hdc;          /* Device-context handle. */
LONG     lStart;        /* First item of information. */
LONG     lCount;        /* Count of items of information. */
PLONG    alArray;       /* Device capabilities. */
BOOL     rc;            /* Success indicator. */

rc = DevQueryCaps(hdc, lStart, lCount, alArray);
```

DevQueryCaps Parameter - hdc

hdc ([HDC](#)) - input
Device-context handle.

DevQueryCaps Parameter - lStart

lStart ([LONG](#)) - input
First item of information.

The number of the first item of information to be returned in *alArray*, counting from zero.

DevQueryCaps Parameter - lCount

ICount (**LONG**) - input
Count of items of information.

This is the count to be returned in *alArray*. It must be greater than zero.

DevQueryCaps Parameter - alArray

alArray (**PLONG**) - output
Device capabilities.

Array of *ICount* elements, starting with *IStart*. The array elements are numbered consecutively, starting with CAPS_FAMILY. The element number constants start with 0.

If *IStart* + *ICount* - 1 exceeds the current highest-defined element number, elements beyond the highest are returned as 0.

CAPS_FAMILY
Device type (values as for *IType* in [DevOpenDC](#)).

CAPS_IO_CAPS
Device input/output capability:

CAPS_IO_DUMMY	Dummy device
CAPS_SUPPORTS_OP	Device supports output
CAPS_SUPPORTS_IP	Device supports input
CAPS_SUPPORTS_IO	Device supports output and input.

CAPS_TECHNOLOGY
Technology:

CAPS_TECH_UNKNOWN	Unknown
CAPS_TECH_VECTOR_PLOTTER	Vector plotter
CAPS_TECH_RASTER_DISPLAY	Raster display
CAPS_TECH_RASTER_PRINTER	Raster printer
CAPS_TECH_RASTER_CAMERA	Raster camera
CAPS_TECH_POSTSCRIPT	PostScript** device.

CAPS_DRIVER_VERSION
Version identifier of the presentation driver.

The high order word of the version identifier is 0. The low order word identifies the release, for example 0x0120 is release 1.2.

CAPS_WIDTH
Media width (for a full screen, maximized window for displays) in pels.

CAPS_HEIGHT
Media depth (for a full screen, maximized window for displays) in pels. (For a plotter, a pel is defined as the smallest possible displacement of the pen and can be smaller than a pen width.)

CAPS_WIDTH_IN_CHARS
Media width (for a full screen, maximized window for displays) in default character columns.

CAPS_HEIGHT_IN_CHARS
Media depth (for a full screen, maximized window for displays) in default character rows.

CAPS_HORIZONTAL_RESOLUTION
Horizontal resolution of device in pels per meter.

CAPS_VERTICAL_RESOLUTION
Vertical resolution of device in pels per meter.

CAPS_CHAR_WIDTH

	Default character-box width in pels for VIO.	
CAPS_CHAR_HEIGHT	Default character-box height in pels for VIO.	
CAPS_SMALL_CHAR_WIDTH	Default small-character box width in pels for VIO. This is 0 if there is only one character-box size.	
CAPS_SMALL_CHAR_HEIGHT	Default small-character box height in pels for VIO. This is 0 if there is only one character-box size.	
CAPS_COLORS	Number of distinct colors supported at the same time, including reset (gray scales count as distinct colors). If loadable color tables are supported, this is the number of entries in the device color table. For plotters, the value returned is the number of pens plus one (for the background).	
CAPS_COLOR_PLANES	Number of color planes.	
CAPS_COLOR_BITCOUNT	Number of adjacent color bits for each pel (within one plane).	
CAPS_COLOR_TABLE_SUPPORT	Loadable color table support:	
	CAPS_COLTABL_RGB_8	1 if RGB color table can be loaded, with a minimum support of 8 bits each for red, green, and blue.
	CAPS_COLTABL_RGB_8_PLUS	1 if color table with other than 8 bits for each primary color can be loaded.
	CAPS_COLTABL_TRUE_MIX	1 if true mixing occurs when the logical color table has been realized, providing that the size of the logical color table is not greater than the number of distinct colors supported (see element CAPS_COLORS).
	CAPS_COLTABL_REALIZE	1 if a loaded color table can be realized.
CAPS_MOUSE_BUTTONS	The number of pointing device buttons that are available. A returned value of 0 indicates that there are no pointing device buttons available.	
CAPS_FOREGROUND_MIX_SUPPORT	Foreground mix support:	
	CAPS_FM_OR	Logical OR.
	CAPS_FM_OVERPAINT	Overpaint.
	CAPS_FM_XOR	Logical XOR.
	CAPS_FM_LEAVEALONE	Leave alone.
	CAPS_FM_AND	Logical AND.
	CAPS_FM_GENERAL_BOOLEAN	All other mix modes; see "GpiSetMix" in <i>Graphics Programming Interface Programming Reference</i> .
	The value returned is the sum of the values appropriate to the mixes supported. A device capable of supporting OR must, as a minimum, return CAPS_FM_OR + CAPS_FM_OVERPAINT + CAPS_FM_LEAVEALONE, signifying support for the mandatory mixes OR, overpaint, and leave-alone.	
	Note that these numbers correspond to the decimal representation of a bit string that is six bits long, with each bit set to 1 if the appropriate mode is supported.	

Those mixes returned as supported are guaranteed for all primitive types. For more information, see "GpiSetMix" in *Graphics Programming Interface Programming Reference*.

CAPS_BACKGROUND_MIX_SUPPORT

Background mix support:

CAPS_BM_OR	Logical OR.
CAPS_BM_OVERPAINT	Overpaint.
CAPS_BM_XOR	Logical XOR.
CAPS_BM_LEAVEALONE	Leave alone.
CAPS_BM_AND	Logical AND.
CAPS_BM_GENERAL_BOOLEAN	All other mix modes; see "GpiSetMix" in <i>Graphics Programming Interface Programming Reference</i> .
CAPS_BM_SRCTRANSSPARENT	Provides a transparent overlay function by not copying pels from the source bit map to the output bit map if they match the presentation space background color.
CAPS_BM_DESTTRANSPARENT	Provides a transparent underlay function by copying only the pels that match the presentation space background color from the source bit map to the output bit map.

The value returned is the sum of the values appropriate to the mixes supported. A device must, as a minimum, return CAPS_BM_OVERPAINT + CAPS_BM_LEAVEALONE, signifying support for the mandatory background mixes overpaint, and leave-alone.

Note that these numbers correspond to the decimal representation of a bit string that is four bits long, with each bit set to 1 if the appropriate mode is supported.

Those mixes returned as supported are guaranteed for all primitive types. For more information, see "GpiSetMix" in *Graphics Programming Interface Programming Reference*.

CAPS_VIO_LOADABLE_FONTS

Number of fonts that can be loaded for VIO.

CAPS_WINDOW_BYTE_ALIGNMENT

Whether or not the client area of VIO windows should be byte-aligned:

CAPS_BYTE_ALIGN_REQUIRED	Must be byte-aligned.
CAPS_BYTE_ALIGN_RECOMMENDED	More efficient if byte-aligned, but not required.
CAPS_BYTE_ALIGN_NOT_REQUIRED	Does not matter whether byte-aligned.

CAPS_BITMAP_FORMATS

Number of bit-map formats supported by device.

CAPS_RASTER_CAPS

Capability for device raster operations:

CAPS_RASTER_BITBLT	1 if GpiBitBlt and GpiWCBitBlt is supported.
CAPS_RASTER_BANDING	1 if banding is supported
CAPS_RASTER_BITBLT_SCALING	1 if GpiBitBlt and GpiWCBitBlt with scaling is supported.
CAPS_RASTER_SET_PEL	1 if GpiSetPel is supported.
CAPS_RASTER_FONTS	1 if this device can draw raster fonts.
CAPS_RASTER_FLOOD_FILL	1 if GpiFloodFill is supported.
CAPS_MARKER_HEIGHT Default marker-box height in pels.	
CAPS_MARKER_WIDTH Default marker-box width in pels.	
CAPS_DEVICE_FONTS Number of device-specific fonts.	
CAPS_GRAPHICS_SUBSET Graphics drawing subset supported. (3 indicates GOCA DR/3)	
CAPS_GRAPHICS_VERSION Graphics architecture version number supported. (1 indicates Version 1)	
CAPS_GRAPHICS_VECTOR_SUBSET Graphics vector drawing subset supported. (2 indicates GOCA VS/2)	
CAPS_DEVICE_WINDOWING Device windowing support:	
CAPS_DEV_WINDOWING_SUPPORT	1 if device supports windowing.
	Other bits are reserved 0.
CAPS_ADDITIONAL_GRAPHICS Additional graphics support:	
CAPS_GRAPHICS_KERNING_SUPPORT	1 if device supports kerning.
CAPS_FONT_OUTLINE_DEFAULT	1 if device has a default outline font.
CAPS_FONT_IMAGE_DEFAULT	1 if device has a default image

	font.
CAPS_SCALED_DEFAULT_MARKERS	1 if default markers are to be scaled by the marker-box attribute.
CAPS_COLOR_CURSOR_SUPPORT	1 if device supports colored cursors.
CAPS_PALETTE_MANAGER	1 if device supports palette functions (see "GpiCreatePalette" in the <i>Graphics Programming Interface Programming Reference</i>).
CAPS_COSMETIC_WIDELINE_SUPPORT	1 if device supports cosmetic thick lines (see "GpiSetLineWidth" in the <i>Graphics Programming Interface Programming Reference</i>).
	Other bits are reserved 0.
CAPS_PHYS_COLORS	Maximum number of distinct colors available on the device.
CAPS_COLOR_INDEX	Maximum logical color-table index supported for this device. For the EGA and VGA drivers, the value is 63.
CAPS_GRAPHICS_CHAR_WIDTH	Default graphics character-box width, in pels.
CAPS_GRAPHICS_CHAR_HEIGHT	Default graphics character-box height, in pels.

CAPS_HORIZONTAL_FONT_RES

Effective horizontal device resolution in pels per inch, for the purpose of selecting fonts.

For printers, this is the actual device resolution, but for displays it may differ from the actual resolution for reasons of legibility.

CAPS_VERTICAL_FONT_RES

Effective vertical device resolution in pels per inch, for the purpose of selecting fonts.

CAPS_DEVICE_FONT_SIM

Identifies which simulations are valid on device fonts.

Valid flags are:

CAPS_DEV_FONT_SIM_BOLD
CAPS_DEV_FONT_SIM_ITALIC
CAPS_DEV_FONT_SIM_UNDERSCORE
CAPS_DEV_FONT_SIM_STRIKEOUT

CAPS_LINEWIDTH_THICK

Cosmetic thickness of lines and arcs on this device, when *fxLineWidth* is LINEWIDTH_THICK (see "GpiSetLineWidth" in the *Graphics Programming Interface Programming Reference*). The units are pels. A value of 0 is interpreted as 2 pels.

CAPS_DEVICE_POLYSET_POINTS

Number of points in a polyset that a device can handle.

DevQueryCaps Return Value - rc

rc (**BOOL**) - returns

Success indicator.

TRUE

Successful completion

FALSE

Error occurred.

DevQueryCaps - Parameters

hdc (**HDC**) - input

Device-context handle.

IStart (**LONG**) - input

First item of information.

The number of the first item of information to be returned in *alArray*, counting from zero.

ICount (**LONG**) - input

Count of items of information.

This is the count to be returned in *alArray*. It must be greater than zero.

alArray (**PLONG**) - output

Device capabilities.

Array of *ICount* elements, starting with *IStart*. The array elements are numbered consecutively, starting with CAPS_FAMILY. The element number constants start with 0.

If */Start + /Count - 1* exceeds the current highest-defined element number, elements beyond the highest are returned as 0.

CAPS_FAMILY

Device type (values as for */Type* in [DevOpenDC](#)).

CAPS_IO_CAPS

Device input/output capability:

CAPS_IO_DUMMY	Dummy device
CAPS_SUPPORTS_OP	Device supports output
CAPS_SUPPORTS_IP	Device supports input
CAPS_SUPPORTS_IO	Device supports output and input.

CAPS_TECHNOLOGY

Technology:

CAPS_Tech_UNKNOWN	Unknown
CAPS_Tech_VECTOR_PLOTTER	Vector plotter
CAPS_Tech_RASTER_DISPLAY	Raster display
CAPS_Tech_RASTER_PRINTER	Raster printer
CAPS_Tech_RASTER_CAMERA	Raster camera
CAPS_Tech_POSTSCRIPT	PostScript** device.

CAPS_DRIVER_VERSION

Version identifier of the presentation driver.

The high order word of the version identifier is 0. The low order word identifies the release, for example 0x0120 is release 1.2.

CAPS_WIDTH

Media width (for a full screen, maximized window for displays) in pels.

CAPS_HEIGHT

Media depth (for a full screen, maximized window for displays) in pels. (For a plotter, a pel is defined as the smallest possible displacement of the pen and can be smaller than a pen width.)

CAPS_WIDTH_IN_CHARS

Media width (for a full screen, maximized window for displays) in default character columns.

CAPS_HEIGHT_IN_CHARS

Media depth (for a full screen, maximized window for displays) in default character rows.

CAPS_HORIZONTAL_RESOLUTION

Horizontal resolution of device in pels per meter.

CAPS_VERTICAL_RESOLUTION

Vertical resolution of device in pels per meter.

CAPS_CHAR_WIDTH

Default character-box width in pels for VIO.

CAPS_CHAR_HEIGHT

Default character-box height in pels for VIO.

CAPS_SMALL_CHAR_WIDTH

Default small-character box width in pels for VIO. This is 0 if there is only one character-box size.

CAPS_SMALL_CHAR_HEIGHT

Default small-character box height in pels for VIO. This is 0 if there is only one character-box size.

CAPS_COLORS

Number of distinct colors supported at the same time, including reset (gray scales count as distinct colors). If loadable color tables are supported, this is the number of entries in the device color table. For plotters, the value returned is the number of pens plus one (for the background).

CAPS_COLOR_PLANES

Number of color planes.

CAPS_COLOR_BITCOUNT

Number of adjacent color bits for each pel (within one plane).

CAPS_COLOR_TABLE_SUPPORT

Loadable color table support:

CAPS_COLTABL_RGB_8	1 if RGB color table can be loaded, with a minimum support of 8 bits each for red, green, and blue.
CAPS_COLTABL_RGB_8_PLUS	1 if color table with other than 8 bits for each primary color can be loaded.
CAPS_COLTABL_TRUE_MIX	1 if true mixing occurs when the logical color table has been realized, providing that the size of the logical color table is not greater than the number of distinct colors supported (see element CAPS_COLORS).
CAPS_COLTABL_REALIZE	1 if a loaded color table can be realized.

CAPS_MOUSE_BUTTONS

The number of pointing device buttons that are available. A returned value of 0 indicates that there are no pointing device buttons available.

CAPS_FOREGROUND_MIX_SUPPORT

Foreground mix support:

CAPS_FM_OR	Logical OR.
CAPS_FM_OVERPAINT	Overpaint.
CAPS_FM_XOR	Logical XOR.
CAPS_FM_LEAVEALONE	Leave alone.
CAPS_FM_AND	Logical AND.
CAPS_FM_GENERAL_BOOLEAN	All other mix modes; see "GpiSetMix" in <i>Graphics Programming Interface Programming Reference</i> .

The value returned is the sum of the values appropriate to the mixes supported. A device capable of supporting OR must, as a minimum, return CAPS_FM_OR + CAPS_FM_OVERPAINT + CAPS_FM_LEAVEALONE, signifying support for the mandatory mixes OR, overpaint, and leave-alone.

Note that these numbers correspond to the decimal representation of a bit string that is six bits long, with each bit set to 1 if the appropriate mode is supported.

Those mixes returned as supported are guaranteed for all primitive types. For more information, see "GpiSetMix" in *Graphics Programming Interface Programming Reference*.

CAPS_BACKGROUND_MIX_SUPPORT

Background mix support:

CAPS_BM_OR	Logical OR.
CAPS_BM_OVERPAINT	Overpaint.
CAPS_BM_XOR	Logical XOR.
CAPS_BM_LEAVEALONE	Leave alone.
CAPS_BM_AND	Logical AND.
CAPS_BM_GENERAL_BOOLEAN	All other mix modes; see "GpiSetMix" in <i>Graphics Programming Interface Programming Reference</i> .

CAPS_BM_SRCTRSPARENT

Provides a transparent overlay function by not copying pels from the source bit map to the output bit map if they match the presentation space background color.

CAPS_BM_DESTTRANSPARENT

Provides a transparent underlay function by copying only the pels that match the presentation space background color from the source bit map to the output bit map.

The value returned is the sum of the values appropriate to the mixes supported. A device must, as a minimum, return CAPS_BM_OVERPAINT + CAPS_BM_LEAVEALONE, signifying support for the mandatory background mixes overpaint, and leave-alone.

Note that these numbers correspond to the decimal representation of a bit string that is four bits long, with each bit set to 1 if the appropriate mode is supported.

Those mixes returned as supported are guaranteed for all primitive types. For more information, see "GpiSetMix" in *Graphics Programming Interface Programming Reference*.

CAPS_VIO_LOADABLE_FONTS

Number of fonts that can be loaded for VIO.

CAPS_WINDOW_BYTE_ALIGNMENT

Whether or not the client area of VIO windows should be byte-aligned:

CAPS_BYTE_ALIGN_REQUIRED

Must be byte-aligned.

CAPS_BYTE_ALIGN_RECOMMENDED

More efficient if byte-aligned, but not required.

CAPS_BYTE_ALIGN_NOT_REQUIRED

Does not matter whether byte-aligned.

CAPS_BITMAP_FORMATS

Number of bit-map formats supported by device.

CAPS_RASTER_CAPS

Capability for device raster operations:

CAPS_RASTER_BITBLT

1 if GpiBitBlt and GpiWCBitBlt is supported.

CAPS_RASTER_BANDING

1 if banding is supported

CAPS_RASTER_BITBLT_SCALING

1 if GpiBitBlt and GpiWCBitBlt with scaling is supported.

CAPS_RASTER_SET_PEL

1 if GpiSetPel is supported.

CAPS_RASTER_FONTS

1 if this device can draw raster fonts.

CAPS_RASTER_FLOOD_FILL

1 if GpiFloodFill

is supported.

CAPS_MARKER_HEIGHT
Default marker-box height in pels.

CAPS_MARKER_WIDTH
Default marker-box width in pels.

CAPS_DEVICE_FONTS
Number of device-specific fonts.

CAPS_GRAPHICS_SUBSET
Graphics drawing subset supported. (3 indicates GOCA DR/3)

CAPS_GRAPHICS_VERSION
Graphics architecture version number supported. (1 indicates Version 1)

CAPS_GRAPHICS_VECTOR_SUBSET
Graphics vector drawing subset supported. (2 indicates GOCA VS/2)

CAPS_DEVICE_WINDOWING
Device windowing support:

CAPS_DEV_WINDOWING_SUPPORT

1 if device
supports
windowing.

Other bits are
reserved 0.

CAPS_ADDITIONAL_GRAPHICS
Additional graphics support:

CAPS_GRAPHICS_KERNING_SUPPORT

1 if
device
supports
kerning.

CAPS_FONT_OUTLINE_DEFAULT

1 if
device
has a
default
outline
font.

CAPS_FONT_IMAGE_DEFAULT

1 if
device
has a
default
image
font.

CAPS_SCALED_DEFAULT_MARKERS

1 if
default
markers
are to be
scaled
by the
marker-
box
attribute.

CAPS_COLOR_CURSOR_SUPPORT

1 if
device
supports
colored
cursors.

CAPS_PALETTE_MANAGER

1 if
device
supports
palette
function

s (see "GpiCreatePalette" in the *Graphics Programming Interface Programming Reference*).

CAPS_COSMETIC_WIDELINE_SUPPORT

1 if device supports cosmetic thick lines (see "GpiSetLineWidth" in the *Graphics Programming Interface Programming Reference*).

Other bits are reserved 0.

CAPS_PHYS_COLORS

Maximum number of distinct colors available on the device.

CAPS_COLOR_INDEX

Maximum logical color-table index supported for this device. For the EGA and VGA drivers, the value is 63.

CAPS_GRAPHICS_CHAR_WIDTH

Default graphics character-box width, in pels.

CAPS_GRAPHICS_CHAR_HEIGHT

Default graphics character-box height, in pels.

CAPS_HORIZONTAL_FONT_RES

Effective horizontal device resolution in pels per inch, for the purpose of selecting fonts.

For printers, this is the actual device resolution, but for displays it may differ from the actual resolution for reasons of legibility.

CAPS_VERTICAL_FONT_RES

Effective vertical device resolution in pels per inch, for the purpose of selecting fonts.

CAPS_DEVICE_FONT_SIM

Identifies which simulations are valid on device fonts.

Valid flags are:

CAPS_DEV_FONT_SIM_BOLD
CAPS_DEV_FONT_SIM_ITALIC
CAPS_DEV_FONT_SIM_UNDERSCORE
CAPS_DEV_FONT_SIM_STRIKEOUT

CAPS_LINEWIDTH_THICK

Cosmetic thickness of lines and arcs on this device, when *fxLineWidth* is LINEWIDTH_THICK (see "GpiSetLineWidth" in the *Graphics Programming Interface Programming Reference*). The units are pels. A value

of 0 is interpreted as 2 pels.

CAPS_DEVICE_POLYSET_POINTS

Number of points in a polyset that a device can handle.

rc ([BOOL](#)) - returns
Success indicator.

TRUE

Successful completion

FALSE

Error occurred.

DevQueryCaps - Remarks

GpiQueryDevice can be used to find the handle of the currently associated device context.

DevQueryCaps - Errors

Possible returns from [WinGetLastError](#)

PMERR_INV_HDC (0x207C)

An invalid device-context handle or (micro presentation space) presentation-space handle was specified.

PMERR_INV_QUERY_ELEMENT_NO (0x20BC)

An invalid start parameter was specified with DevQueryCaps.

PMERR_INV_LENGTH_OR_COUNT (0x2092)

An invalid length or count parameter was specified.

DevQueryCaps - Example Code

In this example the driver is queried to see if it supports input, output, or both. Note that a valid device context handle must be passed. This example assumes a DevOpenDC call has been made to obtain the device context handle.

```
#define INCL_DEV
#include <OS2.H>
```

```

HDC hdc;
LONG lStart;
LONG lCount;
BOOL flreturn;
LONG alArray[CAPS_TECHNOLOGY];
lCount = CAPS_TECHNOLOGY;
lStart = CAPS_FAMILY;

flreturn = DevQueryCaps(hdc,          /* device context handle */
                        lStart,        /* number of first item */
                        lCount,        /* count of items */
                        alArray);      /* array of longs which */
                                      /* will contain the return */
                                      /* information. */

switch(alArray[CAPS_IO_CAPS])        /* we test the CAPS_IO_CAPS */
{                                     /* element of the array to */
    case CAPS_IO_SUPPORTS_OP:        /* find out which options */
                                      /* are supported. */
                                      /* device supports output.*/

    break;

    case CAPS_IO_SUPPORTS_IP:        /* device supports input. */

    break;

    case CAPS_IO_SUPPORTS_IO:        /* device supports both */
                                      /* input and output. */

    break;
    default:
    break;
}

```

DevQueryDeviceNames

DevQueryDeviceNames - Syntax

This function causes a presentation driver to return the names, descriptions, and data types of the devices it supports.

```

#define INCL_DEV /* Or use INCL_PM, */
#include <os2.h>

```

```

HAB      hab;           /* Anchor-block handle. */
PSZ      pszDriverName; /* Fully-qualified name of the file containing the presentation driver. */
PLONG    pldn;          /* Maximum number of device names and descriptions that can be returned. */
PSTR32    aDeviceName;  /* Device-name array. */
PSTR64    aDeviceDesc;  /* Device-description array. */
PLONG     pldt;          /* Maximum number of data types that can be returned. */
PSTR16     aDataType;    /* Data type array. */
BOOL      rc;           /* Success indicator. */

rc = DevQueryDeviceNames(hab, pszDriverName,
                        pldn, aDeviceName, aDeviceDesc, pldt,
                        aDataType);

```

DevQueryDeviceNames Parameter - hab

hab (**HAB**) - input
Anchor-block handle.

DevQueryDeviceNames Parameter - pszDriverName

pszDriverName (**PSZ**) - input
Fully-qualified name of the file containing the presentation driver.

The file-name extension is DRV.

DevQueryDeviceNames Parameter - pldn

pldn (**PLONG**) - in/out
Maximum number of device names and descriptions that can be returned.

On input, it must be greater or equal to 0. *pldn* can have the following values:

Zero	The number of device names and descriptions supported is returned; <i>aDeviceName</i> and <i>aDeviceDesc</i> are not updated.
Nonzero	<i>pldn</i> is updated to the number returned in <i>aDeviceName</i> and <i>aDeviceDesc</i> ; <i>aDeviceName</i> and <i>aDeviceDesc</i> are updated.

DevQueryDeviceNames Parameter - aDeviceName

aDeviceName (**PSTR32**) - output
Device-name array.

An array of null-terminated strings, each element of which identifies a particular device. Valid names are defined by presentation drivers.

DevQueryDeviceNames Parameter - aDeviceDesc

aDeviceDesc (**PSTR64**) - output
Device-description array.

An array of null-terminated strings, each element of which is a description of a particular device. Valid descriptions are defined by presentation drivers.

DevQueryDeviceNames Parameter - pldt

pldt (**PLONG**) - in/out
Maximum number of data types that can be returned.

On input, it must be greater or equal to 0. *pldt* can have the following values:

- | | |
|---------|--|
| Zero | The number of data types supported is returned, and <i>aDataType</i> is not updated. |
| Nonzero | <i>pldt</i> is updated to the number returned, and <i>aDataType</i> is updated. |

DevQueryDeviceNames Parameter - aDataType

aDataType (**PSTR16**) - output
Data type array.

An array of null-terminated strings, each element of which identifies a data type. Valid data types are defined by presentation drivers.

DevQueryDeviceNames Return Value - rc

rc (**BOOL**) - returns
Success indicator.

- | | |
|-------|-----------------------|
| TRUE | Successful completion |
| FALSE | Error occurred. |

DevQueryDeviceNames - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

pszDriverName ([PSZ](#)) - input
Fully-qualified name of the file containing the presentation driver.

The file-name extension is DRV.

pIdn ([PLONG](#)) - in/out
Maximum number of device names and descriptions that can be returned.

On input, it must be greater or equal to 0. *pIdn* can have the following values:

Zero	The number of device names and descriptions supported is returned; <i>aDeviceName</i> and <i>aDeviceDesc</i> are not updated.
Nonzero	<i>pIdn</i> is updated to the number returned in <i>aDeviceName</i> and <i>aDeviceDesc</i> ; <i>aDeviceName</i> and <i>aDeviceDesc</i> are updated.

aDeviceName ([PSTR32](#)) - output
Device-name array.

An array of null-terminated strings, each element of which identifies a particular device. Valid names are defined by presentation drivers.

aDeviceDesc ([PSTR64](#)) - output
Device-description array.

An array of null-terminated strings, each element of which is a description of a particular device. Valid descriptions are defined by presentation drivers.

pIdt ([PLONG](#)) - in/out
Maximum number of data types that can be returned.

On input, it must be greater or equal to 0. *pIdt* can have the following values:

Zero	The number of data types supported is returned, and <i>aDataType</i> is not updated.
Nonzero	<i>pIdt</i> is updated to the number returned, and <i>aDataType</i> is updated.

aDataType ([PSTR16](#)) - output
Data type array.

An array of null-terminated strings, each element of which identifies a data type. Valid data types are defined by presentation drivers.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

DevQueryDeviceNames - Remarks

An application can first call this function with *pIdn* and *pIdt* set to 0 to find how much storage is needed for the data areas. Having allocated the storage, the application calls the function a second time for the data to be entered.

"HP Laserjet IID" is an example of a device name, "Hewlett-Packard Laserjet IID" is an example of a device description, and "PM_Q_STD" is an example of a data type.

DevQueryDeviceNames - Errors

Possible returns from [WinGetLastError](#)

PMERR_INV_LENGTH_OR_COUNT (0x2092)
An invalid length or count parameter was specified.

DevQueryDeviceNames - Example Code

This example uses DevQueryDeviceNames to return the names, descriptions, and data types of supported devices for a presentation driver. The first call to DevQueryDeviceNames determines the number of names, description, and data types available; after allocating the arrays, the second call actually returns the information in the arrays.

```
#define INCL_DEV                /* Device Function definitions */
#define INCL_DOSMEMMGR         /* DOS Memory Manager Functions */
#include <os2.h>

BOOL fSuccess;                /* success indicator */
HAB hab;                      /* Anchor-block handle */
LONG pldn = 0L;               /* number of device names/descriptions */
LONG pldt = 0L;               /* number of data types */
PSTR32 aDeviceName;           /* array of device names */
PSTR64 aDeviceDesc;           /* array of device descriptions */
PSTR16 aDataType;             /* array of data types */

/* query number of supported names/descriptions/data types
(pldn & pldt both 0) */
fSuccess = DevQueryDeviceNames(hab, "IBM4201.DRV", &pldn,
                              aDeviceName, aDeviceDesc, &pldt,
                              aDataType);

if (fSuccess)
{
    /* allocate arrays */
    DosAllocMem((VOID *)aDeviceName, (ULONG)pldn*sizeof(STR32),
                PAG_COMMIT | PAG_WRITE);
    DosAllocMem((VOID *)aDeviceDesc, (ULONG)pldn*sizeof(STR64),
                PAG_COMMIT | PAG_WRITE);
    DosAllocMem((VOID *)aDataType, (ULONG)pldt*sizeof(STR16),
                PAG_COMMIT | PAG_WRITE);

    /* query supported device information */
    fSuccess = DevQueryDeviceNames(hab, "IBM4201.DRV", &pldn,
                                   aDeviceName, aDeviceDesc, &pldt,
                                   aDataType);
}
```

DevQueryHardcopyCaps

DevQueryHardcopyCaps - Syntax

This function queries the hard-copy capabilities of a device.

```
#define INCL_DEV /* Or use INCL_PM, */
#include <os2.h>

HDC      hdc;          /* Device-context handle. */
LONG     lStartForm;    /* Start-forms code. */
LONG     lForms;        /* Number of forms to query. */
PHCIINFO phciHcInfo;    /* Hard-copy capabilities information. */
LONG     lFormsReturned; /* Details of forms: */

lFormsReturned = DevQueryHardcopyCaps(hdc,
                                       lStartForm, lForms, phciHcInfo);
```

DevQueryHardcopyCaps Parameter - hdc

hdc ([HDC](#)) - input
Device-context handle.

DevQueryHardcopyCaps Parameter - lStartForm

IStartForm ([LONG](#)) - input
Start-forms code.

Forms-code number from which the query is to start. The first forms code has the value 0. *IStartForm* is used with *IForms*.

DevQueryHardcopyCaps Parameter - IForms

IForms ([LONG](#)) - input
Number of forms to query.

If 0, the number of forms codes defined is returned. If greater than zero, this function returns the number of forms codes for which information is returned.

For example, if there are five forms codes defined, and *IStartForm* = 2 and *IForms* = 3, a query is performed for forms codes 2, 3, and 4. The result is returned in the buffer pointed to by *phciHcInfo*.

DevQueryHardcopyCaps Parameter - phciHcInfo

phciHcInfo ([PHCINFO](#)) - output
Hard-copy capabilities information.

A buffer containing the results of the query. The result consists of *IForms* copies of the [HCINFO](#) structure.

At least one of the defined forms codes must have the HCAPS_CURRENT bit set. There might be more than one with either the HCAPS_CURRENT or the HCAPS_SELECTABLE bits set.

For a job to be selected by the spooler for printing, each one of the forms specified in the FORM spooler parameter (see *pszSpoolerParams* in [DEVOPENSTRUC](#)) must be either HCAPS_CURRENT or HCAPS_SELECTABLE. In other cases, the spooler holds the job with a "forms mismatch" error.

DevQueryHardcopyCaps Return Value - IFormsReturned

IFormsReturned ([LONG](#)) - returns
Details of forms:

DQHC_ERROR
Error.

>=0
If *IForms* equals 0, number of forms available.
If *IForms* does not equal 0, number of forms returned.

DevQueryHardcopyCaps - Parameters

hdc ([HDC](#)) - input
Device-context handle.

IStartForm ([LONG](#)) - input
Start-forms code.

Forms-code number from which the query is to start. The first forms code has the value 0. *IStartForm* is used with *IForms*.

IForms ([LONG](#)) - input
Number of forms to query.

If 0, the number of forms codes defined is returned. If greater than zero, this function returns the number of forms codes for which information is returned.

For example, if there are five forms codes defined, and *IStartForm* = 2 and *IForms* = 3, a query is performed for forms codes 2, 3, and 4. The result is returned in the buffer pointed to by *phciHcInfo*.

phciHcInfo ([PHCINFO](#)) - output
Hard-copy capabilities information.

A buffer containing the results of the query. The result consists of *IForms* copies of the [HCINFO](#) structure.

At least one of the defined forms codes must have the HCAPS_CURRENT bit set. There might be more than one with either the HCAPS_CURRENT or the HCAPS_SELECTABLE bits set.

For a job to be selected by the spooler for printing, each one of the forms specified in the FORM spooler parameter (see *pszSpoolerParams* in [DEVOPENSTRUC](#)) must be either HCAPS_CURRENT or HCAPS_SELECTABLE. In other cases, the spooler holds the job with a "forms mismatch" error.

IFormsReturned ([LONG](#)) - returns
Details of forms:

DQHC_ERROR
Error.

>=0
If *IForms* equals 0, number of forms available.
If *IForms* does not equal 0, number of forms returned.

DevQueryHardcopyCaps - Errors

Possible returns from [WinGetLastError](#)

PMERR_INV_HDC (0x207C)
An invalid device-context handle or (micro presentation space) presentation-space handle was specified.

PMERR_INV_FORMS_CODE (0x2076)
An invalid forms code parameter was specified with DevQueryHardcopyCaps.

PMERR_INV_LENGTH_OR_COUNT (0x2092)
An invalid length or count parameter was specified.

DevQueryHardcopyCaps - Example Code

The height and width of the capability of the output device is queried for each form code available. Note that a valid device context handle must be passed. This example assumes a DevOpenDC call has been made to obtain the device context handle of a say a printer.

```
#define INCL_DEV
#include <OS2.H>

HDC hdc;
LONG lStartForm;      /* Form code number from which the query */
                     /* is to start */
LONG lForms;          /* number of forms to query */
/* array of structures containing return information. */
HCINFO ahciHcInfo[5];
LONG lreturn;
int i;
HCINFO height[5];
HCINFO width[5];

lStartForm = 0L;
lForms = 0L;          /* the actual number of forms codes is */
                     /* returned. There will be lreturn */
                     /* copies of the HINFO structure. */

lreturn = DevQueryHardcopyCaps(hdc,
                               lStartForm,
                               lForms,
                               ahciHcInfo);

if (lreturn > 5)
{
    lreturn = 5L;      /* we only want the first five form codes */
}                    /* if there are more than five */

for(i = 0; i < lreturn; i++)
{
    width[lreturn].cx = ahciHcInfo[lreturn].cx;
    height[lreturn].cy = ahciHcInfo[lreturn].cy;
}

Direct Manipulation Functions

This section describes functions that an application would use to initiate or participate in a direct manipulation operation.

DrgAcceptDroppedFiles

DrgAcceptDroppedFiles - Syntax

This function handles the file direct manipulation protocol for a given window.

```
#define INCL_WINSTDDRAG
#include <os2.h>

HWND    hwnd;          /* Handle of calling window. */
PSZ     pszPath;       /* Directory in which to place the dropped files. */
PSZ     pszTypes;      /* List of types that are acceptable to the drop. */
ULONG   ulDefaultOp;   /* Default drag operation for this window. */
ULONG   ulRsvd;        /* Reserved. */
BOOL    rc;            /* Success indicator. */

rc = DrgAcceptDroppedFiles(hwnd, pszPath,
                           pszTypes, ulDefaultOp, ulRsvd);
```

DrgAcceptDroppedFiles Parameter - hwnd

hwnd (**HWND**) - input
Handle of calling window.

DrgAcceptDroppedFiles Parameter - pszPath

pszPath (**PSZ**) - input
Directory in which to place the dropped files.

If NULL, the files are placed in the current directory.

DrgAcceptDroppedFiles Parameter - pszTypes

pszTypes (**PSZ**) - input
List of types that are acceptable to the drop.

This string is of the form:

type[, type . . .]

When this pointer is NULL, any type of file will be accepted.

DrgAcceptDroppedFiles Parameter - ulDefaultOp

ulDefaultOp (**ULONG**) - input
Default drag operation for this window.

The operation is either DO_MOVE or DO_COPY.

DrgAcceptDroppedFiles Parameter - ulRsvd

ulRsvd (**ULONG**) - input
Reserved.

DrgAcceptDroppedFiles Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion.
FALSE	Error occurred.

DrgAcceptDroppedFiles - Parameters

hwnd (**HWND**) - input
Handle of calling window.

pszPath (**PSZ**) - input
Directory in which to place the dropped files.

If NULL, the files are placed in the current directory.

pszTypes ([PSZ](#)) - input

List of types that are acceptable to the drop.

This string is of the form:

```
type[ , type. . . ]
```

When this pointer is NULL, any type of file will be accepted.

uiDefaultOp ([ULONG](#)) - input

Default drag operation for this window.

The operation is either DO_MOVE or DO_COPY.

uiRsvd ([ULONG](#)) - input

Reserved.

rc ([BOOL](#)) - returns

Success indicator.

TRUE

Successful completion.

FALSE

Error occurred.

DrgAcceptDroppedFiles - Remarks

This function handles the file direct manipulation protocol for a given window. The window responds ([DOR_DROP](#), *usDefaultOp*) to [DM_DRAGOVER](#) messages for items with a type matching the acceptable type string and with a rendering mechanism and format of <DRM_OS2FILE,DRF_UNKNOWN>. Not all dragged objects must match this criteria for the drop to be acceptable.

After the drop occurs, this function handles the conversation required to complete the direct manipulation operation for all acceptable objects. A [DM_ENDCONVERSATION](#) ([DMFL_TARGETFAIL](#)) message is sent to the source when an object is unacceptable.

When an error occurs during a move or copy, the caller is sent a [DM_DRAGERROR](#) message. The caller can take corrective action.

As the move or copy operation is successfully completed for each file, a [DM_DRAGFILECOMPLETE](#) message is sent to the caller. No message is sent when the operation fails.

The function returns TRUE if the operation is successful and FALSE if an error occurs.

DrgAcceptDroppedFiles - Related Functions

Related Functions

- [DrgDragFiles](#)

DrgAcceptDroppedFiles - Example Code

This example uses the [DrgAcceptDroppedFiles](#) function to define the direct manipulation protocol of the given window, accept all file types, and use the current directory as the drop directory.

```

#define INCL_WINSTDDRAG /* Direct Manipulation (Drag) Functions */
#include <os2.h>

BOOL    fSuccess;        /* Indicate success or failure */
HWND    Hwnd;            /* Handle of calling window */
PSZ     pszPath;         /* Directory in which to place the
                        /* dropped files
PSZ     pszTypes;        /* A list of types that are acceptable
ULONG   ulDefaultOp;     /* Default drag operation

pszPath = NULL;          /* Drop file in current directory
pszTypes = NULL;         /* Accept any file type
ulDefaultOp = DO_MOVE;   /* Default drag operation is move

fSuccess = DrgAcceptDroppedFiles(Hwnd, pszPath, pszTypes,
                                ulDefaultOp, 0);

```

DrgAccessDraginfo

DrgAccessDraginfo - Syntax

This function accesses a [DRAGINFO](#) structure.

```

#define INCL_WINSTDDRAG
#include <os2.h>

PDRAGINFO    pdinfo; /* Pointer to the DRAGINFO structure. */
BOOL         rc;     /* Success indicator. */

rc = DrgAccessDraginfo(pdinfo);

```

DrgAccessDraginfo Parameter - pdinfo

pdinfo ([PDRAGINFO](#)) - input
Pointer to the [DRAGINFO](#) structure.

DrgAccessDraginfo Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion.
FALSE	Error occurred.

DrgAccessDraginfo - Parameters

pdinfo ([PDRAGINFO](#)) - input
Pointer to the [DRAGINFO](#) structure.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion.
FALSE	Error occurred.

DrgAccessDraginfo - Remarks

This function is used by the target of a drag operation to access a [DRAGINFO](#) structure. The address of the structure is passed in a drag message ([DM_DRAGOVER](#), [DM_DROP](#), or [DM_DROPHELP](#)).

To release the structure, use the [DrgFreeDraginfo](#) function.

DrgAccessDraginfo - Errors

Possible returns from [WinGetLastError](#)

PMERR_ACCESS_DENIED (0x150D)	The memory block was not allocated properly.
------------------------------	--

DrgAddStrHandle

DrgAddStrHandle - Syntax

This function creates a handle to a string.

```
#define INCL_WINSTDDRAG
#include <os2.h>

PSZ      pString; /* String for which a handle is to be created. */
HSTR     hstr;    /* String handle. */
```

```
hstr = DrgAddStrHandle(pString);
```

DrgAddStrHandle Parameter - pString

pString ([PSZ](#)) - input
String for which a handle is to be created.

DrgAddStrHandle Return Value - hstr

hstr ([HSTR](#)) - returns
String handle.

NULLHANDLE	Error occurred.
Other	String handle created.

DrgAddStrHandle - Parameters

pString ([PSZ](#)) - input
String for which a handle is to be created.

hstr ([HSTR](#)) - returns
String handle.

NULLHANDLE	Error occurred.
Other	String handle created.

DrgAddStrHandle - Remarks

The handle can be used by any application to reference the input string.

This function must be called by the source of a drag whenever a string is to be passed in a [DRAGINFO](#) structure.

DrgAddStrHandle - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_PARAMETERS (0x1208)

An application parameter value is invalid for its converted PM type. For example: a 4-byte value outside the range -32 768 to +32 767 cannot be converted to a [SHORT](#), and a negative number cannot be converted to a [ULONG](#) or [USHORT](#).

PMERR_RESOURCE_DEPLETION (0x20F9)

An internal resource depletion error has occurred.

DrgAddStrHandle - Example Code

This example calls the DrgAddStrHandle function to create handles for strings that are used in a [DRAGITEM](#) structure.

```
#define INCL_WINSTDDRAG /* Direct Manipulation (Drag) Functions */
#include <os2.h>

USHORT ID_ITEM = 1; /* Drag item identifier */
HWND hwnd; /* Window handle */
DRAGITEM ditem; /* DRAGITEM structure */

/* Initialize the DRAGITEM structure */
ditem.hwndItem = hwnd; /* Conversation partner */
ditem.ulItemID = ID_ITEM; /* Identifies item being dragged */
ditem.hstrType = DrgAddStrHandle(DRT_TEXT); /* Item is text */
ditem.hstrRMF = DrgAddStrHandle("<DRM_OS2FILE,DRF_TEXT>");
ditem.hstrContainerName = DrgAddStrHandle("C:\\");
ditem.hstrSourceName = DrgAddStrHandle("C:\\CONFIG.SYS");
ditem.hstrTargetName = DrgAddStrHandle("C:\\OS2\\CONFIG.SYS");
ditem.cxOffset = 0; /* X-offset of the origin of the */
/* image from the pointer hotspot*/
ditem.cyOffset = 0; /* Y-offset of the origin of the */
/* image from the pointer hotspot*/
ditem.fsControl = 0; /* Source item control flags */
/* object is open */
ditem.fsSupportedOps = 0;
```

[Glossary](#)

DrgAllocDraginfo

DrgAllocDraginfo - Syntax

This function allocates a [DRAGINFO](#) structure.

```
#define INCL_WINSTDDRAG
#include <os2.h>

ULONG      cDitem;    /* Number of objects being dragged. */
PDRAGINFO  Draginfo;  /* Pointer to the DRAGINFO structure. */

Draginfo = DrgAllocDraginfo(cDitem);
```

DrgAllocDraginfo Parameter - cDitem

cDitem ([ULONG](#)) - input
Number of objects being dragged.

This number must be greater than 0.

DrgAllocDraginfo Return Value - Draginfo

Draginfo ([PDRAGINFO](#)) - returns
Pointer to the [DRAGINFO](#) structure.

NULL	Error occurred.
Other	The DRAGINFO structure.

DrgAllocDraginfo - Parameters

cDitem ([ULONG](#)) - input
Number of objects being dragged.

This number must be greater than 0.

Draginfo ([PDRAGINFO](#)) - returns
Pointer to the [DRAGINFO](#) structure.

NULL	Error occurred.
Other	The DRAGINFO structure.

DrgAllocDraginfo - Remarks

This function must be called before the [DrgDrag](#) function is called.

The caller can define a default operation for the objects represented by the [DRAGINFO](#) structure by modifying the *usOperation* field. If the *usOperation* field is modified, the new value will be sent to the target as the operation whenever a DO_DEFAULT operation would normally be sent. The caller should not modify any other part of the [DRAGINFO](#) structure. The [DRAGITEM](#) structures associated with the [DRAGINFO](#) structure should only be altered with [DrgSetDragitem](#) or by using a pointer obtained with [DrgQueryDragitemPtr](#).

DrgAllocDraginfo - Errors

Possible returns from [WinGetLastError](#)

PMERR_INSUFFICIENT_MEMORY (0x203E)
The operation terminated through insufficient memory.

PMERR_INVALID_PARAMETERS (0x1208)
An application parameter value is invalid for its converted PM type. For example: a 4-byte value outside the range -32 768 to +32 767 cannot be converted to a [SHORT](#), and a negative number cannot be converted to a [ULONG](#) or [USHORT](#).

DrgAllocDragtransfer

DrgAllocDragtransfer - Syntax

This function allocates a specified number of [DRAGTRANSFER](#) structures from a single segment.

```
#define INCL_WINSTDDRAG
#include <os2.h>

ULONG          cdxfer;      /* Number of DRAGTRANSFER structures to be allocated. */
PDRAGTRANSFER  pDragtransfer; /* Pointer to an array of DRAGTRANSFER structures. */

pDragtransfer = DrgAllocDragtransfer(cdxfer);
```

DrgAllocDragtransfer Parameter - cdxfer

cdxfer ([ULONG](#)) - input

Number of [DRAGTRANSFER](#) structures to be allocated.

This number must be greater than 0.

DrgAllocDragtransfer Return Value - pDragtransfer

pDragtransfer ([PDRAGTRANSFER](#)) - returns
Pointer to an array of [DRAGTRANSFER](#) structures.

NULL	Error occurred.
Other	The array of DRAGTRANSFER structures.

DrgAllocDragtransfer - Parameters

cdxfer ([ULONG](#)) - input
Number of [DRAGTRANSFER](#) structures to be allocated.

This number must be greater than 0.

pDragtransfer ([PDRAGTRANSFER](#)) - returns
Pointer to an array of [DRAGTRANSFER](#) structures.

NULL	Error occurred.
Other	The array of DRAGTRANSFER structures.

DrgAllocDragtransfer - Remarks

This function must be called before sending a [DM_RENDER](#) message.

DrgAllocDragtransfer - Errors

Possible returns from [WinGetLastError](#)

[PMERR_MEMORY_ALLOCATION_ERR](#) (0x1112)
An error occurred during memory management.

[PMERR_INSUFFICIENT_MEMORY](#) (0x203E)
The operation terminated through insufficient memory.

[PMERR_PARAMETER_OUT_OF_RANGE](#) (0x1003)
The value of a parameter was not within the defined valid range for that parameter.

DrgAllocDragtransfer - Example Code

This example calls the DrgAllocDragtransfer function to allocate a single [DRAGTRANSFER](#) structure and adds a pointer to a [DRAGITEM](#) structure for an object that will be transferred.

```
#define INCL_WINSTDDRAG    /* Direct Manipulation (Drag) Functions*/
#include <os2.h>

PDRAGTRANSFER  pResult;    /* Pointer to DRAGTRANSFER structure    */
PDRAGITEM       pDragitem; /* Pointer to DRAGITEM structure    */

pResult = DrgAllocDragtransfer(1);

if (pResult != NULL)        /* Indicate DRAGITEM to be transferred */
    pResult->pditem = pDragitem;
```

DrgCancelLazyDrag

DrgCancelLazyDrag - Syntax

This function is called to cancel the current drag operation.

```
#define INCL_WINSTDDRAG
#include <os2.h>

BOOL    rc; /* Success indicator. */

rc = DrgCancelLazyDrag();
```

DrgCancelLazyDrag Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

Possible values are described in the following list:

TRUE	Lazy drag is successfully canceled.
FALSE	An error occurred.

DrgCancelLazyDrag - Parameters

rc ([BOOL](#)) - returns
Success indicator.

Possible values are described in the following list:

TRUE	Lazy drag is successfully canceled.
FALSE	An error occurred.

DrgCancelLazyDrag - Remarks

This function posts the [DM_DROPNOTIFY](#) message to the source window, specifying a target window handle of zero in *hwndTarget*. The source window must then free [DRAGINFO](#) using [DrgFreeDraginfo](#).

DrgCancelLazyDrag - Example Code

This example shows the canceling of a lazy drag operation.

```
#define INCL_WINSTDDRAG
#include <os2.h>

BOOL      bResult;          /* Return code from API */

bResult=DrgCancelLazyDrag();
```

DrgDeleteDraginfoStrHandles

DrgDeleteDraginfoStrHandles - Syntax

This function deletes each unique string handle in a [DRAGINFO](#) structure.

```
#define INCL_WINSTDDRAG
#include <os2.h>

PDRAGINFO    pDraginfo; /* Pointer to the DRAGINFO structure that contains string handles to delete. */
BOOL         rc;        /* Success indicator. */

rc = DrgDeleteDraginfoStrHandles(pDraginfo);
```

DrgDeleteDraginfoStrHandles Parameter - pDraginfo

pDraginfo ([PDRAGINFO](#)) - input
Pointer to the [DRAGINFO](#) structure that contains string handles to delete.

DrgDeleteDraginfoStrHandles Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion.
FALSE	Error occurred.

DrgDeleteDraginfoStrHandles - Parameters

pDraginfo ([PDRAGINFO](#)) - input
Pointer to the [DRAGINFO](#) structure that contains string handles to delete.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion.
FALSE	Error occurred.

DrgDeleteDraginfoStrHandles - Remarks

Using this function is equivalent to calling the [DrgDeleteStrHandle](#) function for each unique string in a [DRAGINFO](#) structure.

This function must be called by the target of a direct manipulation operation either:

- After processing a [DM_DROPHELP](#) message
or
- After completing the direct manipulation operation begun as a result of a [DM_DROP](#) message.

DrgDeleteDraginfoStrHandles - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_PARAMETERS (0x1208)
An application parameter value is invalid for its converted PM type. For example: a 4-byte value outside the range -32 768 to +32 767 cannot be converted to a [SHORT](#), and a negative number cannot be converted to a [ULONG](#) or [USHORT](#).

DrgDrag

DrgDrag - Syntax

This function performs a drag operation.

```
#define INCL_WINSTDDRAG
#include <os2.h>

HWND      hwndSource; /* Handle of the source window calling this function. */
PDRAGINFO pdinfo;    /* Pointer to the DRAGINFO structure. */
PDRAGIMAGE pdimg;     /* Pointer to an array of DRAGIMAGE structures. */
ULONG      cdimg;     /* Number of DRAGIMAGE structures in the pdimg array. Must be > 0. */
LONG       vkTerminate; /* Pointing device button that ends the drag operation. */
PVOID      pRsvd;     /* Reserved value, must be NULL. */
HWND       hwndDest;  /* Handle of window on which the dragged objects were dropped. */

hwndDest = DrgDrag(hwndSource, pdinfo, pdimg,
                   cdimg, vkTerminate, pRsvd);
```

DrgDrag Parameter - hwndSource

hwndSource ([HWND](#)) - input
Handle of the source window calling this function.

DrgDrag Parameter - pdinfo

pdinfo ([PDRAGINFO](#)) - in/out
Pointer to the [DRAGINFO](#) structure.

DrgDrag Parameter - pdimg

pdimg ([PDRAGIMAGE](#)) - input
Pointer to an array of [DRAGIMAGE](#) structures.

These structures describe the images that are to be drawn under the direct manipulation pointer during the drag.

DrgDrag Parameter - cdimg

cdimg ([ULONG](#)) - input
Number of [DRAGIMAGE](#) structures in the *pdimg* array. Must be > 0.

DrgDrag Parameter - vkTerminate

vkTerminate ([LONG](#)) - input
Pointing device button that ends the drag operation.

Possible values are described in the following list:

VK_BUTTON1	Release of button 1 ends the drag.
VK_BUTTON2	Release of button 2 ends the drag.
VK_BUTTON3	Release of button 3 ends the drag.
VK_ENDDRAG	Release of the system-defined direct manipulation button ends the drag. This is the recommended value if the DrgDrag function call is invoked in response to a WM_BEGINDRAG message.

DrgDrag Parameter - pRsvd

pRsvd ([PVOID](#)) - input
Reserved value, must be NULL.

DrgDrag Return Value - hwndDest

hwndDest ([HWND](#)) - returns
Handle of window on which the dragged objects were dropped.

A return value of NULL indicates that an error occurred.

DrgDrag - Parameters

hwndSource ([HWND](#)) - input
Handle of the source window calling this function.

pdinfo ([PDRAGINFO](#)) - in/out
Pointer to the [DRAGINFO](#) structure.

pdimg ([PDRAGIMAGE](#)) - input
Pointer to an array of [DRAGIMAGE](#) structures.

These structures describe the images that are to be drawn under the direct manipulation pointer during the drag.

cdimg ([ULONG](#)) - input
Number of [DRAGIMAGE](#) structures in the *pdimg* array. Must be > 0.

vkTerminate ([LONG](#)) - input
Pointing device button that ends the drag operation.

Possible values are described in the following list:

VK_BUTTON1	Release of button 1 ends the drag.
VK_BUTTON2	Release of button 2 ends the drag.
VK_BUTTON3	Release of button 3 ends the drag.
VK_ENDDRAG	Release of the system-defined direct manipulation button ends the drag. This is the recommended value if the DrgDrag function call is invoked in response to a WM_BEGINDRAG message.

pRsvd ([PVOID](#)) - input
Reserved value, must be NULL.

hwndDest ([HWND](#)) - returns
Handle of window on which the dragged objects were dropped.

A return value of NULL indicates that an error occurred.

DrgDrag - Remarks

This function:

- Captures the mouse to the current thread
- Initiates a direct manipulation operation
- Uses the [DRAGIMAGE](#) structure to provide visual feedback to the user during the drag operation
- Notifies other windows as the drag object passes over
- Notifies the destination if the object is dropped
- Releases mouse capture.

Note: DrgDrag will fail if it is unable to capture the mouse. For example, if another window in the same thread has already set the capture.

Before invoking DrgDrag, the caller is responsible for:

- Obtaining a [DRAGINFO](#) structure using [DrgAllocDraginfo](#)
- Initializing the [DRAGITEM](#) structures using [DrgSetDragitem](#).

DrgDrag is called when the system-defined direct-manipulation button is pressed while the pointer is over a window and a pointing device movement follows. As the pointer moves over a potential target, a [DM_DRAGOVER](#) message is sent to the target. When the pointer moves from one target window to another, a [DM_DRAGLEAVE](#) message is sent to the former target.

If the pointer is over a valid target when the direct-manipulation button is released, a [DM_DROP](#) message is sent to the target.

Before the [DM_DROP](#) message is sent, the *cxOffset* and *cyOffset* fields are copied from the [DRAGIMAGE](#) structures to the corresponding fields in the [DRAGITEM](#) structures. The values from the first [DRAGIMAGE](#) are copied to the first [DRAGITEM](#), from the second [DRAGIMAGE](#) to the second [DRAGITEM](#), and so on. The target can use this information to place the images in the same spatial relationship after the drop. If there are more [DRAGITEM](#) structures than there are [DRAGIMAGE](#) structures, the *cxOffset* and *cyOffset* from the final [DRAGIMAGE](#) are placed in each of the remaining [DRAGITEM](#) structures.

The caller can define a default operation for the objects represented by the [DRAGINFO](#) structure by modifying the *usOperation* field. If the *usOperation* field is modified, the new value will be sent to the target as the operation whenever a DO_DEFAULT operation would normally be sent. The caller should not modify any other part of the [DRAGINFO](#) structure. The [DRAGITEM](#) structures associated with the [DRAGINFO](#) structure should only be altered with [DrgSetDragitem](#) or by using a pointer obtained with [DrgQueryDragitemPtr](#).

The following keys are active during the drag operation:

Esc	The drag operation is canceled.
F1	A DM_DROPHELP message is posted to the target so that it can provide context help for the drag operation. The drag operation is canceled.

Once the drag is commenced by calling DrgDrag, neither the image under the pointer nor the objects that comprise the drag set can be modified without canceling the drag and restarting.

On return from DrgDrag, the caller must free the [DRAGINFO](#) structure using [DrgFreeDraginfo](#).

If the dragged objects are not dropped, NULL is returned.

DrgDrag - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

PMERR_INVALID_PARAMETERS (0x1208)
An application parameter value is invalid for its converted PM type. For example: a 4-byte value outside the range -32 768 to +32 767 cannot be converted to a [SHORT](#), and a negative number cannot be converted to a [ULONG](#) or [USHORT](#).

PMERR_INSUFFICIENT_MEMORY (0x203E)
The operation terminated through insufficient memory.

DrgDragFiles

DrgDragFiles - Syntax

This function begins a direct manipulation operation for one or more files.

```

#define INCL_WINSTDDRAG
#include <os2.h>

HWND      Hwnd;          /* Handle of calling window. */
PAPSZ     pFiles;        /* The names of the files to be dragged. */
PAPSZ     pTypes;        /* The file types of the files to be dragged. */
PAPSZ     pTargets;      /* Target file names. */

```

```
ULONG      cFiles;           /* Number of files to be dragged. */
HPOINTER   hptrDrag;        /* Icon to display during the drag. */
ULONG      vkTerm;          /* Button that ends the drag. */
BOOL       fSourceRender;    /* Flag indicating whether the source must perform the move or copy. */
ULONG      ulReserved;       /* Reserved. */
BOOL       rc;               /* Success indicator. */

rc = DrgDragFiles(Hwnd, pFiles, pTypes, pTargets,
                  cFiles, hptrDrag, vkTerm, fSourceRender,
                  ulReserved);
```

DrgDragFiles Parameter - Hwnd

Hwnd ([HWND](#)) - input
Handle of calling window.

DrgDragFiles Parameter - pFiles

pFiles ([PAPSZ](#)) - input
The names of the files to be dragged.

DrgDragFiles Parameter - pTypes

pTypes ([PAPSZ](#)) - input
The file types of the files to be dragged.

DrgDragFiles Parameter - pTargets

pTargets ([PAPSZ](#)) - input
Target file names.

DrgDragFiles Parameter - cFiles

cFiles ([ULONG](#)) - input
Number of files to be dragged.

DrgDragFiles Parameter - hptrDrag

hptrDrag ([HPOINTER](#)) - input
Icon to display during the drag.

DrgDragFiles Parameter - vkTerm

vkTerm ([ULONG](#)) - input
Button that ends the drag.

Possible values are described in the following list:

VK_BUTTON1 Release of button 1 ends the drag.

VK_BUTTON2 Release of button 2 ends the drag.

VK_BUTTON3 Release of button 3 ends the drag.

VK_ENDDRAG Release of the system-defined direct manipulation button ends the drag. This is the recommended value if the [DrgDrag](#) function call is invoked in response to a [WM_BEGINDRAG](#) message.

DrgDragFiles Parameter - fSourceRender

fSourceRender ([BOOL](#)) - input
Flag indicating whether the source must perform the move or copy.

TRUE The caller will receive a [DM_RENDERFILE](#) message for each file.

FALSE All file manipulation is performed by DrgDragFiles.

DrgDragFiles Parameter - ulReserved

ulReserved ([ULONG](#)) - input
Reserved.

DrgDragFiles Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	The drag operation was initiated successfully.
FALSE	An error occurred.

DrgDragFiles - Parameters

Hwnd ([HWND](#)) - input
Handle of calling window.

pFiles ([PAPSZ](#)) - input
The names of the files to be dragged.

pTypes ([PAPSZ](#)) - input
The file types of the files to be dragged.

pTargets ([PAPSZ](#)) - input
Target file names.

cFiles ([ULONG](#)) - input
Number of files to be dragged.

hptrDrag ([HPOINTER](#)) - input
Icon to display during the drag.

vkTerm ([ULONG](#)) - input
Button that ends the drag.

Possible values are described in the following list:

VK_BUTTON1	Release of button 1 ends the drag.
VK_BUTTON2	Release of button 2 ends the drag.
VK_BUTTON3	Release of button 3 ends the drag.
VK_ENDDRAG	Release of the system-defined direct manipulation button ends the drag. This is the recommended value if the DrgDrag function call is invoked in response to a WM_BEGINDRAG message.

fSourceRender ([BOOL](#)) - input
Flag indicating whether the source must perform the move or copy.

TRUE	The caller will receive a DM_RENDERFILE message for each file.
FALSE	All file manipulation is performed by DrgDragFiles.

ulReserved ([ULONG](#)) - input
Reserved.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	The drag operation was initiated successfully.
FALSE	An error occurred.

DrgDragFiles - Remarks

This function begins a direct manipulation operation for one or more files. [DRAGINFO](#) and [DRAGITEM](#) structures are allocated and initialized, and are then used as input to [DrgDrag](#). All of the post-drag conversation required to complete the direct manipulation operation is handled by an object window created by this function.

The caller should set *fSourceRender* to TRUE if it must perform the file manipulation for any of these files. When *fSourceRender* is TRUE, the caller receives a [DM_RENDERFILE](#) message as the drag-object window receives a [DM_RENDER](#) message. The caller should move or copy the file after receiving the [DM_RENDERFILE](#) message. The caller should then send a [DM_FILERENDERED](#) message to the drag-object window, and the drag-object window should send a [DM_RENDERERCOMPLETE](#) message to the target.

When *pTypes* is NULL, the .TYPE EA is interrogated to determine the type for each file in *pFiles*. When *pTypes* is not NULL, the size of the array is expected to be the same as the size of *pFiles*. When any individual pointer in the array is NULL, the .TYPE EA for the corresponding file is read. When .TYPE EA does not exist for any file for which it is needed, a type of DRT_UNKNOWN is used.

When *pTargets* is NULL, the target name for a file will be the same as the source file name with the path information removed. If *pTargets* is not NULL, the size of the array is expected to be the same as the size of *pFiles*. If any individual pointer in the array is NULL, the target name for the corresponding file will match the source name minus the path information.

The rendering mechanism and format for each file is:

```
<DRM_OS2FILE,DRF_UNKNOWN> .
```

When an error occurs during the move or copy, the caller is sent a [DM_DRAGERROR](#) message. The caller can take corrective action.

As the operation is complete for each file in the list, a [DM_DRAGFILECOMPLETE](#) message is sent to the caller of DrgDragFiles. The caller is thus notified that resources can be freed for a particular file.

This function returns TRUE if the drag operation was initiated successfully and FALSE if an error occurred.

TRUE	Successful completion.
FALSE	Error occurred.

DrgFreeDraginfo - Remarks

DrgFreeDraginfo fails with an error of PMERR_SOURCE_SAME_AS_TARGET if it is called by the process that called [DrgDrag](#) before [DrgDrag](#) returns. When a process is performing a drag operation between two of its own windows, this prevents the source window from freeing the [DRAGINFO](#) structure before the target window finishes processing.

DrgFreeDraginfo - Errors

Possible returns from [WinGetLastError](#)

PMERR_MEMORY_DEALLOCATION_ERR (0x1113)
An error occurred during memory management.

PMERR_SOURCE_SAME_AS_TARGET (0x1502)
The direct manipulation source and target process are the same.

DrgFreeDragtransfer

DrgFreeDragtransfer - Syntax

This function frees the storage associated with a [DRAGTRANSFER](#) structure.

```
#define INCL_WINSTDDRAG
#include <os2.h>

PDRAGTRANSFER    pdxfer; /* Pointer to the DRAGTRANSFER structures to be freed. */
BOOL              rc;     /* Return code. */

rc = DrgFreeDragtransfer(pdxfer);
```

DrgFreeDragtransfer Parameter - pdxfer

pdxfer ([PDRAGTRANSFER](#)) - input
Pointer to the [DRAGTRANSFER](#) structures to be freed.

DrgFreeDragtransfer Return Value - rc

rc ([BOOL](#)) - returns
Return code.

TRUE	The structure was freed successfully.
FALSE	The deallocation failed.

DrgFreeDragtransfer - Parameters

pdxfer ([PDRAGTRANSFER](#)) - input
Pointer to the [DRAGTRANSFER](#) structures to be freed.

rc ([BOOL](#)) - returns
Return code.

TRUE	The structure was freed successfully.
FALSE	The deallocation failed.

DrgFreeDragtransfer - Remarks

This function frees the [DRAGTRANSFER](#) structures allocated by calls to [DrgAllocDragtransfer](#). When all of the [DRAGTRANSFER](#)

structures have been freed, the memory block containing the [DRAGTRANSFER](#) array is deallocated.

DrgFreeDragtransfer - Errors

Possible returns from [WinGetLastError](#)

PMERR_MEMORY_DEALLOCATION_ERR (0x1113)
An error occurred during memory management.

DrgGetPS

DrgGetPS - Syntax

This function gets a presentation space that is used to provide target feedback to the user during a drag operation.

```
#define INCL_WINSTDDRAG
#include <os2.h>

HWND    hwnd; /* Handle of the window for which presentation space is required. */
HPS     Hps;  /* Presentation-space handle used for drawing in the window. */

Hps = DrgGetPS(hwnd);
```

DrgGetPS Parameter - hwnd

hwnd (**HWND**) - input
Handle of the window for which presentation space is required.

DrgGetPS Return Value - Hps

Hps (**HPS**) - returns
Presentation-space handle used for drawing in the window.

NULLHANDLE
Error occurred.

DrgGetPS - Parameters

hwnd (**HWND**) - input
Handle of the window for which presentation space is required.

Hps (**HPS**) - returns
Presentation-space handle used for drawing in the window.

NULLHANDLE
Error occurred.

DrgGetPS - Remarks

This function returns a handle to a presentation space that can be used for drawing while a direct manipulation operation is in progress.

DrgGetPS is called only during a direct manipulation operation. This function is called only after a [DM_DRAGOVER](#), [DM_DRAGLEAVE](#), or [DM_DROP](#) message has been received.

In order to draw target emphasis, an application must use DrgGetPS and [DrgReleasePS](#) to unlock its window.

The presentation space created with DrgGetPS must be freed with [DrgReleasePS](#).

DrgGetPS - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

PMERR_NOT_DRAGGING (0x1f00)
A drag operation is not in progress at this time.

DrgLazyDrag

DrgLazyDrag - Syntax

DrgLazyDrag is called when a direct-manipulation button is pressed while the lazy drag augmentation key is held to initiate a pickup and drop (lazy drag) operation.

```
#define INCL_WINSTDDRAG
#include <os2.h>

HWND      hwndSource; /* Handle of the source window that is calling this function. */
PDRAGINFO pdinfo;     /* Pointer to the DRAGINFO structure which contains information about the objects being dragged. */
PDRAGIMAGE pdimg;      /* Pointer to an array of DRAGIMAGE structures. */
ULONG      cdimg;       /* Number of DRAGIMAGE structures in the pdimg array. */
PVOID      pRsvd;       /* Reserved value, must be 0. */
BOOL       rc;          /* Success indicator. */

rc = DrgLazyDrag(hwndSource, pdinfo, pdimg,
                  cdimg, pRsvd);
```

DrgLazyDrag Parameter - hwndSource

hwndSource ([HWND](#)) - input
Handle of the source window that is calling this function.

DrgLazyDrag Parameter - pdinfo

pdinfo ([PDRAGINFO](#)) - input
Pointer to the [DRAGINFO](#) structure which contains information about the objects being dragged.

DrgLazyDrag Parameter - pdimg

pdimg ([PDRAGIMAGE](#)) - input
Pointer to an array of [DRAGIMAGE](#) structures.

These structures describe the images that are to be drawn under the direct-manipulation pointer during the drag.

DrgLazyDrag Parameter - cdimg

cdimg ([ULONG](#)) - input
Number of [DRAGIMAGE](#) structures in the *pdimg* array.

DrgLazyDrag Parameter - pRsvd

pRsvd ([PVOID](#)) - input
Reserved value, must be 0.

DrgLazyDrag Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

Possible values are described in the following list:

- | | |
|-------|---|
| TRUE | A lazy drag operation was successfully started. |
| FALSE | An error occurred while initiating a lazy drag operation. |

DrgLazyDrag - Parameters

hwndSource ([HWND](#)) - input
Handle of the source window that is calling this function.

pdinfo ([PDRAGINFO](#)) - input
Pointer to the [DRAGINFO](#) structure which contains information about the objects being dragged.

pdimg ([PDRAGIMAGE](#)) - input
Pointer to an array of [DRAGIMAGE](#) structures.

These structures describe the images that are to be drawn under the direct-manipulation pointer during the drag.

cdimg ([ULONG](#)) - input
Number of [DRAGIMAGE](#) structures in the *pdimg* array.

pRsvd ([PVOID](#)) - input

Reserved value, must be 0.

rc (**BOOL**) - returns
Success indicator.

Possible values are described in the following list:

TRUE	A lazy drag operation was successfully started.
FALSE	An error occurred while initiating a lazy drag operation.

DrgLazyDrag - Remarks

Before initiating a lazy drag operation by calling `DrgLazyDrag`, the application must allocate the **DRAGINFO** structure using `DrgAllocDraginfo`.

`DrgLazyDrag` is called when the direct-manipulation button is pressed while holding down the lazy drag augmentation key, currently the ALT key. As the pointer moves over a potential target, a **DM_DRAGOVER** message is sent to the target window. When the pointer moves from one target window to another, a **DM_DRAGLEAVE** message is sent to the former target.

If the pointer is over a valid window target when the direct-manipulation button is pressed and the lazy drag "end drag" augmentation key (Ctrl+Shift to link, Ctrl to copy and Shift to move) is pressed, a **DM_DROP** message is sent to the target window. The source window posts a **DM_DROPNOTIFY** message, informing the target window that a drop has occurred.

param2 parameter of **DM_DROPNOTIFY** message contains the handle of the target window that the drag set was dropped on. If *param2* is zero, the drag set was not dropped; in other words, the drag operation was canceled. The source window must check *pDraginfo* to see if the target window is different from the source. If the source and target are different, the source window must free **DRAGINFO** upon receipt of the **DM_DROPNOTIFY** message. If the source and target window handles are the same, the target must free the **DRAGINFO** after completing the post-drop conversation.

The caller can define a default operation for the objects represented by the **DRAGINFO** structure by modifying its *usOperate* field. If *usOperate* is modified, the new value is sent to the target as the operation when a NO_DEFAULT operation would normally be sent. The caller must not modify any other part of the **DRAGINFO** structure. The **DRAGITEM** structures associated with the **DRAGINFO** structure must only be altered with `DrgSetDragitem` or by using a pointer obtained from `DrgQueryDragitemPtr`.

A window receives a **WM_PICKUP** message when the direct-manipulation button is pressed holding down the lazy drag augmentation key. In response to this message, an application is responsible for:

- Obtaining a **DRAGINFO** structure using `DrgAllocDraginfo`
- Initializing the **DRAGITEM** structures using `DrgSetDragitem`.

Objects are added to the drag set whenever a **WM_PICKUP** message is received. The first time that message is received, the application must call `DrgLazyDrag` to begin the lazy drag operation. Each subsequent **WM_PICKUP** message that is received during the course of a lazy drag operation indicates that objects are to be added to the drag set. If objects are currently being dragged, the application must reallocate the **DRAGINFO** structure using `DrgReallocDragInfo`. `DrgReallocDragInfo` frees the current **DRAGINFO** and allocates a new one. The lazy drag operation can then continue by making another call to `DrgLazyDrag`.

Objects can also be removed from the drag set during the course of a lazy drag operation. It is the application's responsibility to define what action initiates such a "putback" operation; for example, if a "pickup" operation executed while the pointer is not over a valid object. It is the application's responsibility to decide if a putback operation may apply to individual objects within the drag set or the drag set as a whole. If the putback operation is applied to the drag set as a whole, the result is the same as canceling the drag. If the put-back operation is applied to individual objects within the drag set, the application must free the **DRAGINFO** and reallocate it to represent the new state of the drag set. If the drag operation is to continue, the application must make another call to `DrgLazyDrag`.

`DrgLazyDrag` returns as soon as it completes initialization for the drag. The pointing device remains active during a lazy drag and can be used in the same manner as if no drag operation were in progress. As soon as `DrgLazyDrag` returns, the application can free its **DRAGIMAGE** array.

Note: Because the lazy drag operation is nonmodal, the mouse pointer may be used as if no drag operation were in progress.

Once a standard drag operation is commenced by calling `DrgDrag`, the objects that comprise the drag set cannot be modified without canceling the drag and restarting. The drag set can be modified during the course of the drag operation. When the drag set is modified, the application must reallocate the **DRAGINFO** structure and make another call to `DrgLazyDrag`.

Note: The mouse changes to an arrow with an attache case attached to the lower right-hand corner when the lazy drag is in progress, rather

than a stack of images shown during a standard drag.

The *pdimg* and *cdimg* parameters were added for compatibility with [DrgDrag](#) only.

DrgLazyDrop

DrgLazyDrop - Syntax

This function is called to invoke a lazy drop operation.

```

#define INCL_WINSTDDRAG
#include <os2.h>

HWND      hwndTarget; /* Handle of the target window receiving the drop. */
ULONG     ulOperation; /* Drop operation code. */
PPOINTL   pptlDrop;    /* Pointer to the drop location in desktop coordinates. */
BOOL      rc;          /* Success indicator. */

rc = DrgLazyDrop(hwndTarget, ulOperation,
                 pptlDrop);

```

DrgLazyDrop Parameter - hwndTarget

hwndTarget (HWND) - input
Handle of the target window receiving the drop.

DrgLazyDrop Parameter - ulOperation

ulOperation (ULONG) - input
Drop operation code.

Possible values are shown in the following list:

DO_DEFAULT	Default operation.
DO_COPY	Operation is a copy.
DO_MOVE	Operation is a move.
DO_LINK	Operation is a link.

DrgLazyDrop Parameter - pptIDrop

pptIDrop (PPOINTL) - input
Pointer to the drop location in desktop coordinates.

DrgLazyDrop Return Value - rc

rc (BOOL) - returns
Success indicator.

TRUE	Objects are successfully dropped.	.
FALSE	An error occurred.	

DrgLazyDrop - Parameters

hwndTarget (**HWND**) - input
Handle of the target window receiving the drop.

ulOperation (**ULONG**) - input
Drop operation code.

Possible values are shown in the following list:

- DO_DEFAULT** Default operation.
- DO_COPY** Operation is a copy.
- DO_MOVE** Operation is a move.
- DO_LINK** Operation is a link.

ptlDrop (**POINTL**) - input
Pointer to the drop location in desktop coordinates.

rc (**BOOL**) - returns
Success indicator.

- TRUE** Objects are successfully dropped.
- FALSE** An error occurred.

DrgLazyDrop - Remarks

This function can be used to implement a "drop" choice from a menu.

DrgLazyDrop - Example Code

This example uses DrgLazyDrop to perform a drop to a target window, using the copy operation.

```
#define INCL_WINSTDDRAG
#include <os2.h>

HWND      hwndTarget;    /* Handle of the Target window */
ULONG     ulDropOp;      /* Operation to be performed on the drop */
POINTL    ptlDrop;       /* Drop location */
BOOL      bSuccess;      /* Return code from API */

ptlDrop.x=5;
ptlDrop.y=10;

usDropOp=DO_COPY;
bSuccess=DrgLazyDrop(hwndTarget, ulDropOp, &ptlDrop);
```

DrgPostTransferMsg

DrgPostTransferMsg - Syntax

This function posts a message to the other application involved in the direct manipulation operation.

```
#define INCL_WINSTDDRAG
#include <os2.h>

HWND      hwnd;      /* Window handle to which the message      is to be posted. */
ULONG     msg;       /* Identifier of the message to be posted. */
PDRAGTRANSFER pdxfer; /* Pointer to the DRAGTRANSFER structure. */
ULONG     fl;        /* Flags to be passed in the param2 parameter of the message identified by msg. */
ULONG     ulRsvd;    /* Reserved value, must be 0. */
BOOL      fRetry;    /* Retry indicator. */
BOOL      rc;        /* Success indicator. */

rc = DrgPostTransferMsg(hwnd, msg, pdxfer,
                        fl, ulRsvd, fRetry);
```

DrgPostTransferMsg Parameter - hwnd

hwnd (**HWND**) - input
Window handle to which the message is to be posted.

Target
hwndItem in the **DRAGITEM** structure.

Source
hwndClient in the **DRAGTRANSFER** structure.

DrgPostTransferMsg Parameter - msg

msg (**ULONG**) - input
Identifier of the message to be posted.

DM_RENDERCOMPLETE is the only valid message.

DrgPostTransferMsg Parameter - pdxfer

pdxfer ([PDRAGTRANSFER](#)) - input
Pointer to the [DRAGTRANSFER](#) structure.

DrgPostTransferMsg Parameter - fl

fl ([ULONG](#)) - input
Flags to be passed in the *param2* parameter of the message identified by *msg*.

DrgPostTransferMsg Parameter - ulRsvd

ulRsvd ([ULONG](#)) - input
Reserved value, must be 0.

DrgPostTransferMsg Parameter - fRetry

fRetry ([BOOL](#)) - input
Retry indicator.

TRUE	<p>If the destination queue is full, the message posting is retried at 1-second intervals until the message is posted successfully.</p> <p>In this case, DrgPostTransferMsg dispatches any messages in the queue by calling WinPeekMsg and WinDispatchMsg in a loop. The application can receive messages sent by other applications while it is trying to post drag transfer messages.</p>
FALSE	<p>The call returns FALSE without retrying.</p>

DrgPostTransferMsg Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE

FALSE	Successful completion.
	Error occurred.

DrgPostTransferMsg - Parameters

hwnd ([HWND](#)) - input
Window handle to which the message is to be posted.

Target
hwndItem in the [DRAGITEM](#) structure.

Source
hwndClient in the [DRAGTRANSFER](#) structure.

msg ([ULONG](#)) - input
Identifier of the message to be posted.

[DM_RENDERCOMPLETE](#) is the only valid message.

pdxfer ([PDRAGTRANSFER](#)) - input
Pointer to the [DRAGTRANSFER](#) structure.

fl ([ULONG](#)) - input
Flags to be passed in the *param2* parameter of the message identified by *msg*.

ulRsvd ([ULONG](#)) - input
Reserved value, must be 0.

fRetry ([BOOL](#)) - input
Retry indicator.

TRUE
If the destination queue is full, the message posting is retried at 1-second intervals until the message is posted successfully.

In this case, DrgPostTransferMsg dispatches any messages in the queue by calling [WinPeekMsg](#) and [WinDispatchMsg](#) in a loop. The application can receive messages sent by other applications while it is trying to post drag transfer messages.

FALSE
The call returns FALSE without retrying.

rc ([BOOL](#)) - returns
Success indicator.

TRUE
Successful completion.

FALSE
Error occurred.

DrgPostTransferMsg - Remarks

The *fsReply* field in the [DRAGTRANSFER](#) structure is set to 0 before the message is posted. If the posting fails for any reason, FALSE is returned.

DrgPushDraginfo

DrgPushDraginfo - Syntax

This function gives a process access to a [DRAGINFO](#) structure.

```
#define INCL_WINSTDDRAG
#include <os2.h>

PDRAGINFO    pdinfo;    /* Pointer to the DRAGINFO structure. */
HWND         hwndDest;  /* Handle of the window whose process is to be given access to a DRAGINFO structure. */
BOOL         rc;        /* Success indicator. */

rc = DrgPushDraginfo(pdinfo, hwndDest);
```

DrgPushDraginfo Parameter - pdinfo

pdinfo ([PDRAGINFO](#)) - input
Pointer to the [DRAGINFO](#) structure.

DrgPushDraginfo Parameter - hwndDest

hwndDest ([HWND](#)) - input
Handle of the window whose process is to be given access to a [DRAGINFO](#) structure.

DrgPushDraginfo Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion.
FALSE	Error occurred.

DrgPushDraginfo - Parameters

pdinfo ([PDRAGINFO](#)) - input
Pointer to the [DRAGINFO](#) structure.

hwndDest ([HWND](#)) - input
Handle of the window whose process is to be given access to a [DRAGINFO](#) structure.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion.
FALSE	Error occurred.

DrgPushDraginfo - Remarks

The receiving process is responsible for:

1. Deleting the string handles in the [DRAGINFO](#) structure with [DrgDeleteDraginfoStrHandles](#)
2. Freeing the [DRAGINFO](#) structure using [DrgFreeDraginfo](#).

DrgPushDraginfo - Errors

Possible returns from [WinGetLastError](#)

PMERR_ACCESS_DENIED (0x150D)
The memory block was not allocated properly.

PMERR_INSUFFICIENT_MEMORY (0x203E)
The operation terminated through insufficient memory.

- [DrgFreeDraginfo](#)

DrgPushDraginfo - Example Code

This example calls the [DrgPushDraginfo](#) function to grant access to a [DRAGINFO](#) structure to the process owning the specified window handle. The [DRAGINFO](#) structure was previously allocated using the [DrgAllocDraginfo](#) function.

```

#define INCL_WINSTDDRAG /* Direct Manipulation (Drag) Functions */
#include <os2.h>

BOOL      fSuccess;      /* Indicate success or failure */
DRAGINFO  Draginfo;      /* Pointer to DRAGINFO structure */
HWND      hwndDest;      /* Handle of window whose process will */
                        /* will be given access to the DRAGINFO */
                        /* structure */

fSuccess = DrgPushDraginfo(&Draginfo,hwndDest);

```

DrgQueryDraginfoPtr

DrgQueryDraginfoPtr - Syntax

This function obtains a pointer to the current [DRAGINFO](#) structure.

```

#define INCL_WINSTDDRAG
#include <os2.h>

PDRAGINFO  pRsvd;      /* Reserved value, must be NULL. */
PDRAGINFO  pDragInfo;  /* Pointer to the current DRAGINFO structure. */

pDragInfo = DrgQueryDraginfoPtr(pRsvd);

```

DrgQueryDraginfoPtr Parameter - pRsvd

pRsvd ([PDRAGINFO](#)) - input
 Reserved value, must be NULL.

DrgQueryDraginfoPtr Return Value - pDragInfo

pDragInfo ([PDRAGINFO](#)) - returns
Pointer to the current [DRAGINFO](#) structure.

A return value of NULL indicates that a [DRAGINFO](#) has not been allocated.

DrgQueryDraginfoPtr - Parameters

pRsvd ([PDRAGINFO](#)) - input
Reserved value, must be NULL.

pDragInfo ([PDRAGINFO](#)) - returns
Pointer to the current [DRAGINFO](#) structure.

A return value of NULL indicates that a [DRAGINFO](#) has not been allocated.

DrgQueryDraginfoPtr - Remarks

The returned [DRAGINFO](#) structure could have been allocated for use in either a standard or lazy drag operation. [DrgQueryDragStatus](#) can be used to determine which type of drag is active.

DrgQueryDraginfoPtrFromDragitem

DrgQueryDraginfoPtrFromDragitem - Syntax

This function is called to obtain a pointer to the [DRAGINFO](#) structure associated with a given [DRAGITEM](#) structure.

```
#define INCL_WINSTDDRAG
#include <os2.h>

PDRAGITEM    pditem;      /* Pointer to a DRAGITEM structure whose corresponding DRAGINFO is to be returned. */
PDRAGINFO    pDraginfo;   /* Pointer to the DRAGINFO structure for the specified pditem. */

pDraginfo = DrgQueryDraginfoPtrFromDragitem(
    pditem);
```

DrgQueryDraginfoPtrFromDragitem Parameter - pditem

pditem ([PDRAGITEM](#)) - input

Pointer to a [DRAGITEM](#) structure whose corresponding [DRAGINFO](#) is to be returned.

DrgQueryDraginfoPtrFromDragitem Return Value - pDraginfo

pDraginfo ([PDRAGINFO](#)) - returns
Pointer to the [DRAGINFO](#) structure for the specified *pditem*.

A return value of NULL indicates that a [DRAGITEM](#) structure was not found.

DrgQueryDraginfoPtrFromDragitem - Parameters

pditem ([PDRAGITEM](#)) - input
Pointer to a [DRAGITEM](#) structure whose corresponding [DRAGINFO](#) is to be returned.

pDraginfo ([PDRAGINFO](#)) - returns
Pointer to the [DRAGINFO](#) structure for the specified *pditem*.

A return value of NULL indicates that a [DRAGITEM](#) structure was not found.

DrgQueryDraginfoPtrFromDragitem - Example Code

This example uses DrgQueryDraginfoPtrFromDragitem to obtain the pointer to the [DRAGINFO](#) structure associated with a given [DRAGITEM](#) structure. The example assumes the application already has a pointer to one of the [DRAGITEM](#) structures.

```
#define INCL_WINSTDDRAG
#include <os2.h>

PDRAGINFO pdinfo;          /* Pointer to a DRAGINFO structure */
PDRAGITEM pdragitem;        /* Pointer to a DRAGITEM structure */

DrgQueryDraginfoPtrFromHwnd

DrgQueryDraginfoPtrFromHwnd - Syntax

This function determines whether a particular window has allocated a [DRAGINFO](#) structure.

```
#define INCL_WINSTDDRAG
#include <os2.h>

HWND      hwndSource; /* Handle of the window whose associated DRAGINFO pointer is to be returned.
PDRAGINFO  pDraginfo; /* Pointer to the DRAGINFO structure allocated by the window specified by hwndSource.

pDraginfo = DrgQueryDraginfoPtrFromHwnd(hwndSource);
```

DrgQueryDraginfoPtrFromHwnd Parameter - hwndSource

hwndSource ([HWND](#)) - input
Handle of the window whose associated [DRAGINFO](#) pointer is to be returned.

DrgQueryDraginfoPtrFromHwnd Return Value - pDraginfo

pDraginfo ([PDRAGINFO](#)) - returns
Pointer to the [DRAGINFO](#) structure allocated by the window specified by *hwndSource*.
If the return value is NULL, the [DRAGINFO](#) structure has not been allocated.

DrgQueryDraginfoPtrFromHwnd - Parameters

hwndSource ([HWND](#)) - input
Handle of the window whose associated [DRAGINFO](#) pointer is to be returned.

pDraginfo ([PDRAGINFO](#)) - returns
Pointer to the [DRAGINFO](#) structure allocated by the window specified by *hwndSource*.
If the return value is NULL, the [DRAGINFO](#) structure has not been allocated.

DrgQueryDraginfoPtrFromHwnd - Remarks

The application can gain access to the structure [DRAGINFO](#) by calling [DrgAccessDraginfo](#).

DrgQueryDraginfoPtrFromHwnd - Example Code

This example uses DrgQueryDraginfoPtrFromHwnd to obtain a pointer to the [DRAGINFO](#) structure allocated by the given window.

```
#define INCL_WINSTDDRAG
#include <os2.h>

HWND      hwndWindow;    /* Window handle */
PDRAGINFO pinfo;         /* Pointer to a DRAGINFO structure */

DrgQueryDragitem

DrgQueryDragitem - Syntax

This function returns a [DRAGITEM](#) structure used in the direct manipulation operation.

```
#define INCL_WINSTDDRAG
#include <os2.h>

PDRAGINFO    pdinfo;    /* Pointer to the DRAGINFO structure from which the DRAGITEM structure is obtained. */
ULONG        cbBuffer;  /* Maximum number of bytes to copy to the buffer. */
PDRAGITEM    pditem;    /* Pointer to the buffer into which the DRAGITEM structure is copied. */
ULONG        iItem;     /* Zero-based index of the DRAGITEM to be returned. */
BOOL         rc;        /* Success indicator. */

rc = DrgQueryDragitem(pdinfo, cbBuffer, pditem,
    iItem);
```

DrgQueryDragitem Parameter - pinfo

pinfo (**PDRAGINFO**) - input
Pointer to the **DRAGINFO** structure from which the **DRAGITEM** structure is obtained.

DrgQueryDragitem Parameter - cbBuffer

cbBuffer (**ULONG**) - input
Maximum number of bytes to copy to the buffer.

DrgQueryDragitem Parameter - pditem

pditem (**PDRAGITEM**) - output
Pointer to the buffer into which the **DRAGITEM** structure is copied.

DrgQueryDragitem Parameter - item

item (**ULONG**) - input
Zero-based index of the **DRAGITEM** to be returned.

DrgQueryDragitem Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion.
FALSE	Error occurred.

DrgQueryDragitem - Parameters

pdinfo ([PDRAGINFO](#)) - input
Pointer to the [DRAGINFO](#) structure from which the [DRAGITEM](#) structure is obtained.

cbBuffer ([ULONG](#)) - input
Maximum number of bytes to copy to the buffer.

pditem ([PDRAGITEM](#)) - output
Pointer to the buffer into which the [DRAGITEM](#) structure is copied.

ilitem ([ULONG](#)) - input
Zero-based index of the [DRAGITEM](#) to be returned.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion.
FALSE	Error occurred.

DrgQueryDragitem - Remarks

This function returns the [DRAGITEM](#) structure identified by *ilitem*.

DrgQueryDragitemCount

DrgQueryDragitemCount - Syntax

This function returns the number of objects being dragged during the current direct manipulation operation.

```
#define INCL_WINSTDDRAG
#include <os2.h>

PDRAGINFO    pdinfo; /* Pointer to the DRAGINFO structure for which number of dragged objects is requested. */
ULONG        cDitem; /* Number of objects being dragged. */

cDitem = DrgQueryDragitemCount(pdinfo);
```

DrgQueryDragitemCount Parameter - pdinfo

pdinfo ([PDRAGINFO](#)) - input

Pointer to the [DRAGINFO](#) structure for which number of dragged objects is requested.

DrgQueryDragitemCount Return Value - cDitem

cDitem ([ULONG](#)) - returns

Number of objects being dragged.

DrgQueryDragitemCount - Parameters

pdinfo ([PDRAGINFO](#)) - input
Pointer to the [DRAGINFO](#) structure for which number of dragged objects is requested.

cDitem ([ULONG](#)) - returns
Number of objects being dragged.

DrgQueryDragitemCount - Example Code

This example calls the DrgQueryDragitemCount function to return the number of [DRAGITEM](#) structures in the corresponding [DRAGINFO](#) structure, which maps to the number of objects being dragged.

```
#define INCL_WINSTDDRAG /* Direct Manipulation (Drag) Functions */
#include <os2.h>

ULONG      cDitem;      /* Number of objects being dragged      */
DRAGINFO   Draginfo;    /* DRAGINFO structure queried for the    */
                        /* number of drag objects                */

cDitem = DrgQueryDragitemCount(&Draginfo);

DrgQueryDragitemPtr

DrgQueryDragitemPtr - Syntax

This function returns a pointer to the [DRAGITEM](#) structure used in the direct manipulation operation.

```
#define INCL_WINSTDDRAG
#include <os2.h>
```

```
PDRAGINFO    pdinfo;      /* Pointer to the DRAGINFO structure from which the DRAGITEM structure is obtained. */
ULONG        ulIndex;     /* Zero-based index of the DRAGITEM structure for which the pointer is to be returned. */
PDRAGITEM    Dragitem;     /* Pointer to the DRAGITEM structure. */
```

```
Dragitem = DrgQueryDragitemPtr(pdinfo, ulIndex);
```

DrgQueryDragitemPtr Parameter - pdinfo

pdinfo (**PDRAGINFO**) - input

Pointer to the **DRAGINFO** structure from which the **DRAGITEM** structure is obtained.

DrgQueryDragitemPtr Parameter - ulIndex

ulIndex (**ULONG**) - input

Zero-based index of the **DRAGITEM** structure for which the pointer is to be returned.

DrgQueryDragitemPtr Return Value - Dragitem

Dragitem (**PDRAGITEM**) - returns

Pointer to the **DRAGITEM** structure.

DrgQueryDragitemPtr - Parameters

pdinfo (**PDRAGINFO**) - input

Pointer to the **DRAGINFO** structure from which the **DRAGITEM** structure is obtained.

ulIndex (**ULONG**) - input

Zero-based index of the **DRAGITEM** structure for which the pointer is to be returned.

Dragitem (**PDRAGITEM**) - returns

Pointer to the **DRAGITEM** structure.

DrgQueryDragitemPtr - Remarks

This function returns a pointer to *ulItemID* in the **DRAGITEM** structure used in the direct manipulation operation.

DrgQueryDragStatus

DrgQueryDragStatus - Syntax

This function determines the status of the current drag operation.

```
#define INCL_WINSTDDRAG
#include <os2.h>

ULONG rc; /* Flag indicating the current drag status. */

rc = DrgQueryDragStatus();
```

DrgQueryDragStatus Return Value - rc

rc (ULONG) - returns
Flag indicating the current drag status.

Possible values are shown in the following list:

0	A drag operation is not currently in progress.
DGS_DRAGINPROGRESS	A standard drag operation is in progress.
DGS_LAZYDRAGINPROGRESS	A lazy drag operation is in progress.

DrgQueryDragStatus - Parameters

rc (ULONG) - returns
Flag indicating the current drag status.

Possible values are shown in the following list:

0	A drag operation is not currently in progress.
DGS_DRAGINPROGRESS	A standard drag operation is in progress.
DGS_LAZYDRAGINPROGRESS	A lazy drag operation is in progress.

DrgQueryDragStatus - Example Code

This example uses DrgQueryDragStatus to determine whether a lazy drag operation is currently in progress.

```
#define INCL_WINSTDDRAG
#include <os2.h>

if (DrgQueryDragStatus() & DGS_LAZYDRAGINPROGRESS)
{
    .
    . /* Lazy drag is in progress */

DrgQueryNativeRMF

DrgQueryNativeRMF - Syntax

Obtains the ordered pair that represents the native rendering mechanism and format of the dragged object.

```
#define INCL_WINSTDDRAG
#include <os2.h>

PDRAGITEM    pditem;    /* Pointer to the DRAGITEM structure. */
ULONG        cbBuffer;  /* Maximum number of bytes to copy to the buffer. */
PCHAR        pBuffer;   /* Pointer to the buffer in which the null-terminated string is to be returned. */
BOOL         rc;        /* Success indicator. */

rc = DrgQueryNativeRMF(pditem, cbBuffer, pBuffer);
```

DrgQueryNativeRMF Parameter - pditem

pditem ([PDRAGITEM](#)) - input
Pointer to the [DRAGITEM](#) structure.

Pointer to the [DRAGITEM](#) structure whose native rendering mechanism and format are to be obtained.

DrgQueryNativeRMF Parameter - cbBuffer

cbBuffer ([ULONG](#)) - input
Maximum number of bytes to copy to the buffer.

DrgQueryNativeRMF Parameter - pBuffer

pBuffer ([PCHAR](#)) - output
Pointer to the buffer in which the null-terminated string is to be returned.

DrgQueryNativeRMF Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion.
FALSE	Error occurred.

DrgQueryNativeRMF - Parameters

pditem ([PDRAGITEM](#)) - input
Pointer to the [DRAGITEM](#) structure.

Pointer to the [DRAGITEM](#) structure whose native rendering mechanism and format are to be obtained.

cbBuffer ([ULONG](#)) - input
Maximum number of bytes to copy to the buffer.

pBuffer ([PCHAR](#)) - output
Pointer to the buffer in which the null-terminated string is to be returned.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion.
FALSE	Error occurred.

DrgQueryNativeRMF - Remarks

If the rendering mechanism and format string for the object are NULL, FALSE is returned. If TRUE is returned, the format of the string is:

```
(mechanism(1)[,mechanism(n)...]),  
(format(1)[,format(n)...])
```

The native rendering mechanism and format are the first ordered pair, or the first ordered pair produced by a cross product, in the string associated with *hstrRMF* in the [DRAGITEM](#) structure.

[DrgQueryNativeRMFLen](#) can be used to determine the size of the buffer required to hold the string returned by this function.

DrgQueryNativeRMF - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_PARAMETERS (0x1208)

An application parameter value is invalid for its converted PM type. For example: a 4-byte value outside the range -32 768 to +32 767 cannot be converted to a [SHORT](#), and a negative number cannot be converted to a [ULONG](#) or [USHORT](#).

DrgQueryNativeRMFLen

DrgQueryNativeRMFLen - Syntax

Obtains the length of the string representing the native rendering mechanism and format of the dragged object.

```
#define INCL_WINSTDDRAG
#include <os2.h>

PDRAGITEM    pditem;    /* Pointer to the DRAGITEM structure whose native rendering mechanism and format string
ULONG        ulLength;  /* String length of the ordered pair. */

ulLength = DrgQueryNativeRMFLen(pditem);
```

DrgQueryNativeRMFLen Parameter - pditem

pditem ([PDRAGITEM](#)) - input
Pointer to the [DRAGITEM](#) structure whose native rendering mechanism and format string length are to be obtained.

DrgQueryNativeRMFLen Return Value - ulLength

ulLength ([ULONG](#)) - returns
String length of the ordered pair.

0	Error occurred.
Other	String length of the ordered pair, excluding the null-terminating byte.

DrgQueryNativeRMFLen - Parameters

pditem ([PDRAGITEM](#)) - input
Pointer to the [DRAGITEM](#) structure whose native rendering mechanism and format string length are to be obtained.

uiLength ([ULONG](#)) - returns
String length of the ordered pair.

- 0
Error occurred.
- Other
String length of the ordered pair, excluding the null-terminating byte.

DrgQueryNativeRMFLen - Remarks

This function is used to determine the size of the buffer that contains the string representing the native rendering mechanism and format of the dragged object.

If the input string handle is NULLHANDLE or not valid, a length of 0 is returned.

DrgQueryNativeRMFLen - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_PARAMETERS (0x1208)
An application parameter value is invalid for its converted PM type. For example: a 4-byte value outside the range -32 768 to +32 767 cannot be converted to a [SHORT](#), and a negative number cannot be converted to a [ULONG](#) or [USHORT](#).

DrgQueryStrName

DrgQueryStrName - Syntax

This function gets the contents of a string associated with a string handle.

```

#define INCL_WINSTDDRAG
#include <os2.h>

HSTR      hstr;      /* The handle must have been created with DrgAddStrHandle. */
ULONG     cbBuffer;  /* Maximum number of bytes to copy into pBuffer. */
PSZ       pBuffer;   /* Buffer where the null-terminated string is returned. */
ULONG     ulLength;  /* Number of bytes written to pBuffer. */

ulLength = DrgQueryStrName(hstr, cbBuffer,
                           pBuffer);

```

DrgQueryStrName Parameter - hstr

hstr ([HSTR](#)) - input

The handle must have been created with [DrgAddStrHandle](#).

DrgQueryStrName Parameter - cbBuffer

cbBuffer ([ULONG](#)) - input

Maximum number of bytes to copy into *pBuffer*.

Must be greater than 0. Otherwise, an error is returned.

DrgQueryStrName Parameter - pBuffer

pBuffer ([PSZ](#)) - output

Buffer where the null-terminated string is returned.

DrgQueryStrName Return Value - ulLength

ulLength ([ULONG](#)) - returns

Number of bytes written to *pBuffer*.

DrgQueryStrName - Parameters

hstr ([HSTR](#)) - input

The handle must have been created with [DrgAddStrHandle](#).

cbBuffer ([ULONG](#)) - input

Maximum number of bytes to copy into *pBuffer*.

Must be greater than 0. Otherwise, an error is returned.

pBuffer ([PSZ](#)) - output

Buffer where the null-terminated string is returned.

ulLength ([ULONG](#)) - returns

Number of bytes written to *pBuffer*.

DrgQueryStrName - Remarks

This function should be called whenever the contents of a string referenced by a drag string handle are required. If the input string handle is

NULLHANDLE or not valid, a null string is returned.

DrgQueryStrName - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_PARAMETERS (0x1208)

An application parameter value is invalid for its converted PM type. For example: a 4-byte value outside the range -32 768 to +32 767 cannot be converted to a [SHORT](#), and a negative number cannot be converted to a [ULONG](#) or [USHORT](#).

DrgQueryStrNameLen

DrgQueryStrNameLen - Syntax

This function gets the length of a string associated with a string handle.

```
#define INCL_WINSTDDRAG
#include <os2.h>

HSTR      hstr;      /* String handle. */
ULONG     cLength;   /* Length of the string associated with hstr. */

cLength = DrgQueryStrNameLen(hstr);
```

DrgQueryStrNameLen Parameter - hstr

hstr ([HSTR](#)) - input
String handle.

The handle must be created with [DrgAddStrHandle](#).

DrgQueryStrNameLen Return Value - cLength

cLength ([ULONG](#)) - returns
Length of the string associated with *hstr*.

0	The string handle is NULLHANDLE or is not valid.
Other	The length of the string associated with the string handle, excluding the null terminating byte.

DrgQueryStrNameLen - Parameters

hstr ([HSTR](#)) - input
String handle.

The handle must be created with [DrgAddStrHandle](#).

cLength ([ULONG](#)) - returns
Length of the string associated with *hstr*.

0	The string handle is NULLHANDLE or is not valid.
Other	The length of the string associated with the string handle, excluding the null terminating byte.

DrgQueryStrNameLen - Remarks

This function should be called before calling the [DrgQueryStrName](#) function. It is used to determine and allocate the buffer size for the string associated with the string handle. If the input string handle is NULLHANDLE or not valid, a length of 0 is returned.

DrgQueryStrNameLen - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_PARAMETERS (0x1208)
An application parameter value is invalid for its converted PM type. For example: a 4-byte value outside the range -32 768 to +32 767 cannot be converted to a [SHORT](#), and a negative number cannot be converted to a [ULONG](#) or [USHORT](#).

DrgQueryTrueType

DrgQueryTrueType - Syntax

This function obtains the true type of a dragged object.

```
#define INCL_WINSTDDRAG
#include <os2.h>

PDRAITEM    pditem; /* Pointer to the DRAGITEM structure whose type is to be obtained. */
```

```
ULONG      cbBuffer; /* Maximum number of bytes to copy to pBuffer. Must be > 0. */
PSZ        pBuffer; /* Buffer in which the null-terminated string is to be returned. */
BOOL       rc;      /* Success indicator. */

rc = DrgQueryTrueType(pditem, cbBuffer, pBuffer);
```

DrgQueryTrueType Parameter - pditem

pditem (**PDRAGITEM**) - input
Pointer to the **DRAGITEM** structure whose type is to be obtained.

DrgQueryTrueType Parameter - cbBuffer

cbBuffer (**ULONG**) - input
Maximum number of bytes to copy to *pBuffer*. Must be > 0.

DrgQueryTrueType Parameter - pBuffer

pBuffer (**PSZ**) - output
Buffer in which the null-terminated string is to be returned.

DrgQueryTrueType Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion.
FALSE	Error occurred.

DrgQueryTrueType - Parameters

pditem (**PDRAGITEM**) - input
Pointer to the **DRAGITEM** structure whose type is to be obtained.

cbBuffer ([ULONG](#)) - input
Maximum number of bytes to copy to *pBuffer*. Must be > 0.

pBuffer ([PSZ](#)) - output
Buffer in which the null-terminated string is to be returned.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	
FALSE	Successful completion.
	Error occurred.

DrgQueryTrueType - Remarks

The true type of an object is the first type in the string referenced by *hstrType* in the [DRAGITEM](#) structure.

This function can be called after calling the [DrgQueryTrueTypeLen](#) function. If the type string for the object is NULLHANDLE, FALSE is returned.

DrgQueryTrueType - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_PARAMETERS (0x1208)
An application parameter value is invalid for its converted PM type. For example: a 4-byte value outside the range -32 768 to +32 767 cannot be converted to a [SHORT](#), and a negative number cannot be converted to a [ULONG](#) or [USHORT](#).

DrgQueryTrueTypeLen

DrgQueryTrueTypeLen - Syntax

This function obtains the length of the string that represents the true type of a dragged object.

```

#define INCL_WINSTDDRAG
#include <os2.h>

PDRAGITEM    pditem; /* Pointer to the DRAGITEM structure whose type length is to be obtained. */
ULONG        ulLength; /* String length of the first element of the character string associated with hstrType

ulLength = DrgQueryTrueTypeLen(pditem);

```

DrgQueryTrueTypeLen Parameter - pditem

pditem ([PDRAGITEM](#)) - input
 Pointer to the [DRAGITEM](#) structure whose type length is to be obtained.

DrgQueryTrueTypeLen Return Value - ulLength

ulLength ([ULONG](#)) - returns
String length of the first element of the character string associated with *hstrType*.

0	Error occurred.
Other	The length of the first element of the character string associated with <i>hstrType</i> , excluding the null-terminating byte.

DrgQueryTrueTypeLen - Parameters

pditem ([PDRAGITEM](#)) - input
Pointer to the [DRAGITEM](#) structure whose type length is to be obtained.

ulLength ([ULONG](#)) - returns
String length of the first element of the character string associated with *hstrType*.

0	Error occurred.
Other	The length of the first element of the character string associated with <i>hstrType</i> , excluding the null-terminating byte.

DrgQueryTrueTypeLen - Remarks

This function can be used to determine the buffer size to allocate for the string representing the true type of a dragged object. The true type of an object is the first type in the type string referenced by *hstrType* in the [DRAGITEM](#) structure.

This function can be called before calling the [DrgQueryTrueType](#) function.

If the input string handle is NULLHANDLE or not valid, a length of 0 is returned.

DrgQueryTrueTypeLen - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_PARAMETERS (0x1208)
An application parameter value is invalid for its converted PM type. For example: a 4-byte value outside the range -32 768 to +32 767 cannot be converted to a [SHORT](#), and a negative number cannot be converted to a [ULONG](#) or [USHORT](#).

DrgReallocDragInfo

DrgReallocDragInfo - Syntax

This function releases the current [DRAGINFO](#) structure and reallocates a new one.

```
#define INCL_WINSTDDRAG
#include <os2.h>

PDRAGINFO pdrinfoOld; /* Pointer to the current DRAGINFO structure. */
ULONG     cditem; /* Number of DRAGITEM structures to be allocated. */
PDRAGINFO pdrinfoCurrent; /* Pointer to a newly allocated DRAGINFO structure. */
```

```
pdinfoCurrent = DrgReallocDragInfo(pdinfoOld,  
                                   cditem);
```

DrgReallocDragInfo Parameter - pdinfoOld

pdinfoOld ([PDRAGINFO](#)) - input
Pointer to the current [DRAGINFO](#) structure.

DrgReallocDragInfo Parameter - cditem

cditem ([ULONG](#)) - input
Number of [DRAGITEM](#) structures to be allocated.

DrgReallocDragInfo Return Value - pdinfoCurrent

pdinfoCurrent ([PDRAGINFO](#)) - returns
Pointer to a newly allocated [DRAGINFO](#) structure.

DrgReallocDragInfo - Parameters

pdinfoOld ([PDRAGINFO](#)) - input
Pointer to the current [DRAGINFO](#) structure.

cditem ([ULONG](#)) - input
Number of [DRAGITEM](#) structures to be allocated.

pdinfoCurrent ([PDRAGINFO](#)) - returns
Pointer to a newly allocated [DRAGINFO](#) structure.

DrgReallocDragInfo - Remarks

It is necessary to call `DrgReallocDragInfo` anytime objects are added or deleted from the current lazy drag set. This function unconditionally frees the old [DRAGINFO](#) structure, reallocates a new [DRAGINFO](#) structure, and returns a pointer to the new structure.

Note: This function does not check if the source and target window handles are different; it unconditionally frees the [DRAGINFO](#) structure passed to it.

DrgReallocDragInfo - Related Functions

Related Functions

- [DrgAllocDraginfo](#)
-

DrgReallocDragInfo - Example Code

This example uses DrgReallocDragInfo to reallocate the [DRAGINFO](#) structure when an object is picked up or added to the lazy drag set. It checks whether a lazy drag operation is already in progress, and if so, adds one to the number of objects currently being dragged and calls DrgReallocDragInfo to obtain a new [DRAGINFO](#) structure with the required number of [DRAGITEM](#) structures.

```
#define INCL_WINSTDDRAG
#include <os2.h>

PDRAGINFO pdinfoCurrent; /* Pointer to the current DRAGINFO */
PDRAGINFO pdinfoOld; /* Pointer to the DRAGINFO to be freed */
ULONG cditem; /* Number of DRAGITEMS */
.
.
.
case WM_PICKUP:

    if (DrgQueryDragStatus() & DGS_LAZYDRAGINPROGRESS)
    {
        /* Get a pinter to the current DRAGINFO structure */
        pdinfoOld=DrgQueryDraginfoPtr(NULL);

        /* Add space for one more DRAGITEM */
        cditem=pdinfoOld->cditem+1;

        /* Reallocate the DRAGINFO */
        pdinfoCurrent=DrgReallocDraginfo(pdinfoOld, cditem);
        if(pdinfoCurrent)
        {
            /* Continue the lazy drag operation */
            DrgLazyDrag( ... )
        }
    }
}
```

DrgReleasePS

DrgReleasePS - Syntax

This function releases a presentation space obtained by using the [DrgGetPS](#) function.

```
#define INCL_WINSTDDRAG
#include <os2.h>

HPS    hps; /* Handle of the presentation space to release. */
BOOL    rc; /* Success indicator. */

rc = DrgReleasePS(hps);
```

DrgReleasePS Parameter - hps

hps ([HPS](#)) - input
Handle of the presentation space to release.

DrgReleasePS Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion.
FALSE	Error occurred.

DrgReleasePS - Parameters

hps ([HPS](#)) - input
Handle of the presentation space to release.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion.
------	------------------------

FALSE

Error occurred.

DrgReleasePS - Remarks

Only presentation spaces created with [DrgGetPS](#) can be released using this function.

The presentation-space handle should not be used after this function.

DrgReleasePS - Errors

Possible returns from [WinGetLastError](#)

PMERR_INV_HPS (0x207F)

An invalid presentation-space handle was specified.

PMERR_NOT_DRAGGING (0x1f00)

A drag operation is not in progress at this time.

DrgReleasePS - Related Functions

Prerequisite Functions

DrgSendTransferMsg

DrgSendTransferMsg - Syntax

This function sends a message to the other application involved in the direct manipulation operation.

```
#define INCL_WINSTDDRAG
#include <os2.h>

HWND      hwndTo;      /* Window handle to which the message is to be sent. */
ULONG     ulMsgid;     /* Identifier of the message to be sent. */
MPARAM    mpParam1;    /* First message parameter. */
MPARAM    mpParam2;    /* Second message parameter. */
MRESULT   mresReply;   /* Message-return data. */

mresReply = DrgSendTransferMsg(hwndTo, ulMsgid,
                               mpParam1, mpParam2);
```

DrgSendTransferMsg Parameter - hwndTo

hwndTo ([HWND](#)) - input

Window handle to which the message is to be sent.

Target

hwndItem in the [DRAGITEM](#) structure.

Source

hwndClient in the [DRAGTRANSFER](#) structure.

DrgSendTransferMsg Parameter - ulMsgid

ulMsgid ([ULONG](#)) - input

Identifier of the message to be sent.

Valid messages are:

DM_ENDCONVERSATION
DM_RENDER
DM_RENDERPREPARE

DrgSendTransferMsg Parameter - mpParam1

mpParam1 ([MPARAM](#)) - input
First message parameter.

DrgSendTransferMsg Parameter - mpParam2

mpParam2 ([MPARAM](#)) - input
Second message parameter.

DrgSendTransferMsg Return Value - mresReply

mresReply ([MRESULT](#)) - returns
Message-return data.

DrgSendTransferMsg - Parameters

hwndTo ([HWND](#)) - input
Window handle to which the message is to be sent.

Target
hwndItem in the [DRAGITEM](#) structure.

Source
hwndClient in the [DRAGTRANSFER](#) structure.

ulMsgid ([ULONG](#)) - input
Identifier of the message to be sent.

Valid messages are:

DM_ENDCONVERSATION
DM_RENDER
DM_RENDERPREPARE

mpParam1 ([MPARAM](#)) - input
First message parameter.

mpParam2 ([MPARAM](#)) - input
Second message parameter.

mresReply ([MRESULT](#)) - returns
Message-return data.

DrgSendTransferMsg - Remarks

If the message to be sent is [DM_RENDER](#) or [DM_RENDERCOMPLETE](#), the *fsReply* field in [DRAGTRANSFER](#) is set to 0 before the message is sent. If the message cannot be sent, FALSE is returned.

When the message to be sent is [DM_RENDER](#), DosGiveSeg is called. DosGiveSeg gives access to the [DRAGTRANSFER](#) structure to the process that owns the window indicated by *hwndTo*. The use count for the segment in which the [DRAGTRANSFER](#) structure exists is incremented.

The process to which the message is being sent must call [DrgFreeDragtransfer](#) for the [DRAGTRANSFER](#) structure before the segment can be freed.

DrgSetDragImage

DrgSetDragImage - Syntax

This function sets the image that is being dragged.

```
#define INCL_WINSTDDRAG
#include <os2.h>

PDRAGINFO    pdinfo; /* Pointer to the DRAGINFO structure representing the drag operation for which the pointer is to be set. */
PDRAGIMAGE    pdimg; /* Pointer to an array of DRAGIMAGE structures. */
ULONG        cdimg; /* Number of DRAGIMAGE structures in the pdimg array. */
PVOID        pRsvd; /* Reserved value, must be NULL. */
BOOL         rc; /* Success indicator. */

rc = DrgSetDragImage(pdinfo, pdimg, cdimg,
                    pRsvd);
```

DrgSetDragImage Parameter - pdinfo

pdinfo ([PDRAGINFO](#)) - input
Pointer to the [DRAGINFO](#) structure representing the drag operation for which the pointer is to be set.

DrgSetDragImage Parameter - pdimg

pdimg ([PDRAGIMAGE](#)) - input
Pointer to an array of [DRAGIMAGE](#) structures.

These structures describe the images to be drawn under the pointer during the drag.

DrgSetDragImage Parameter - cdimg

cdimg ([ULONG](#)) - input
Number of [DRAGIMAGE](#) structures in the *pdimg* array.

DrgSetDragImage Parameter - pRsvd

pRsvd ([PVOID](#)) - input
Reserved value, must be NULL.

DrgSetDragImage Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion.
FALSE	Error occurred.

DrgSetDragImage - Parameters

pdinfo ([PDRAGINFO](#)) - input
Pointer to the [DRAGINFO](#) structure representing the drag operation for which the pointer is to be set.

pdimg ([PDRAGIMAGE](#)) - input
Pointer to an array of [DRAGIMAGE](#) structures.

These structures describe the images to be drawn under the pointer during the drag.

cdimg ([ULONG](#)) - input
Number of [DRAGIMAGE](#) structures in the *pdimg* array.

pRsvd ([PVOID](#)) - input
Reserved value, must be NULL.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion.
FALSE	Error occurred.

DrgSetDragImage - Remarks

The image that is set with DrgSetDragImage is used only while the pointer is over the target that made the call. If the pointer leaves the original target, the new target can specify an image by calling DrgSetDragImage.

If the new target does not call DrgSetDragImage, the original image that was supplied on the call to [DrgDrag](#) is used.

DrgSetDragImage - Errors

Possible returns from [WinGetLastError](#)

PMERR_ACCESS_DENIED (0x150D)

The memory block was not allocated properly.

PMERR_INVALID_PARAMETERS (0x1208)

An application parameter value is invalid for its converted PM type. For example: a 4-byte value outside the range -32 768 to +32 767 cannot be converted to a [SHORT](#), and a negative number cannot be converted to a [ULONG](#) or [USHORT](#).

PMERR_INSUFFICIENT_MEMORY (0x203E)

The operation terminated through insufficient memory.

DrgSetDragImage - Example Code

This example sets the icon image that is displayed during a direct manipulation operation.

```
#define INCL_GPIBITMAPS /* GPI Bit Map Functions */
#define INCL_WINSTDDRAG /* Direct Manipulation (Drag) Functions */
#include <os2.h>
#define ID_BITMAP 257 /* .rc file: "bitmap 257 drgimage.bmp" */
HPS hps; /* Presentation space handle */
BOOL flResult;
HAB hab;
PDRAGINFO pdinfo;
DRAGIMAGE dimg;
HBITMAP hbm; /* Bit-map handle */
HWND hwnd;

/*****
 * Load a bit map for use as a drag image
 *****/

case WM_CREATE:
    hps = WinGetPS(hwnd);

    hbm = GpiLoadBitmap(hps, 0L, ID_BITMAP, 20L, 20L);
    WinReleasePS(hps);
    break;

case DM_DRAGOVER:
/*****
 * Initialize the DRAGIMAGE structure
 *****/

    dimg.cb = sizeof(DRAGIMAGE); /* Size control block */
    dimg.cptl = 0;
    dimg.hImage = hbm; /* Image handle passed to */
    /* DrgDrag */
    dimg.sizlStretch.cx = 20L; /* Size to stretch ico or */
    dimg.sizlStretch.cy = 20L; /* bmp to */
    dimg.fl = DRG_BITMAP |
        DRG_STRETCH; /* Stretch to size specified */
    dimg.cxOffset = 0; /* Offset of the origin of */
    dimg.cyOffset = 0; /* the image from the pointer*/
    /* hotspot */

/*****
```

```
/* Set the drag image */
/*****
flResult= DrgSetDragImage(pdinfo,&dimg,(ULONG)sizeof(dimg), NULL);
```

DrgSetDragitem

DrgSetDragitem - Syntax

This function sets the values in a [DRAGITEM](#) structure.

```
#define INCL_WINSTDDRAG
#include <os2.h>

PDRAGINFO    pdinfo;    /* Pointer to the DRAGINFO structure in which to place the DRAGITEM. */
PDRAGITEM    pditem;    /* Pointer to the DRAGITEM structure to place in DRAGINFO. */
ULONG        cbBuffer;  /* Size of the DRAGITEM addressed by pditem. */
ULONG        iItem;     /* Zero-based index of the DRAGITEM to be set. */
BOOL         rc;        /* Success indicator. */

rc = DrgSetDragitem(pdinfo, pditem, cbBuffer,
                    iItem);
```

DrgSetDragitem Parameter - pdinfo

pdinfo ([PDRAGINFO](#)) - input

Pointer to the [DRAGINFO](#) structure in which to place the [DRAGITEM](#).

DrgSetDragitem Parameter - pditem

pditem (**PDRAGITEM**) - input
Pointer to the **DRAGITEM** structure to place in **DRAGINFO**.

DrgSetDragitem Parameter - cbBuffer

cbBuffer (**ULONG**) - input
Size of the **DRAGITEM** addressed by *pditem*.

DrgSetDragitem Parameter - iltem

iltem (**ULONG**) - input
Zero-based index of the **DRAGITEM** to be set.

DrgSetDragitem Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion.
FALSE	Error occurred.

DrgSetDragitem - Parameters

pdinfo (**PDRAGINFO**) - input
Pointer to the **DRAGINFO** structure in which to place the **DRAGITEM**.

pditem (**PDRAGITEM**) - input
Pointer to the **DRAGITEM** structure to place in **DRAGINFO**.

cbBuffer (**ULONG**) - input
Size of the **DRAGITEM** addressed by *pditem*.

iltem (**ULONG**) - input
Zero-based index of the **DRAGITEM** to be set.

rc (**BOOL**) - returns
Success indicator.

TRUE

FALSE Successful completion.
 Error occurred.

DrgSetDragitem - Remarks

This function is used to initialize the [DRAGINFO](#) structure before calling [DrgDrag](#).

This function is used only by the source of the drag, not by the target.

DrgSetDragPointer

DrgSetDragPointer - Syntax

This function sets the pointer to be used while over the current target.

```

#define INCL_WINSTDDRAG
#include <os2.h>

PDRAGINFO    pdinfo; /* Pointer to the DRAGINFO structure to be used for this drag. */
HPOINTER     hptr;   /* Handle to the pointer to use. */
BOOL         rc;      /* Success indicator. */

rc = DrgSetDragPointer(pdinfo, hptr);

```

DrgSetDragPointer Parameter - pdinfo

pdinfo (**PDRAGINFO**) - input
Pointer to the **DRAGINFO** structure to be used for this drag.

DrgSetDragPointer Parameter - hptr

hptr (**HPOINTER**) - input
Handle to the pointer to use.

DrgSetDragPointer Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion.
FALSE	Error occurred.

DrgSetDragPointer - Parameters

pdinfo (**PDRAGINFO**) - input
Pointer to the **DRAGINFO** structure to be used for this drag.

hptr (**HPOINTER**) - input
Handle to the pointer to use.

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion.
FALSE	Error occurred.

DrgSetDragPointer - Remarks

This function sets the pointer to be used to indicate the hot spot while dragging over the current target.

The pointer that is set with DrgSetDragPointer is used only while it is over the current target. The pointer is reset to the default when a new target is dragged over.

This function can be used by an application to provide meaningful augmentation emphasis for an operation that is unknown to the system

(for example, swap).

When the drag pointer is successfully set, TRUE is returned.

DrgSetDragPointer - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HPTR (0x101B)
An invalid pointer handle was specified.

DrgVerifyNativeRMF

DrgVerifyNativeRMF - Syntax

Determines if the native rendering mechanism and format of an object match any supplied by the application.

```
#define INCL_WINSTDDRAG
#include <os2.h>

PDRAGITEM    pDragitem; /* Pointer to the DRAGITEM structure. whose native rendering mechanism and format are
PSZ           pRMF;      /* A string specifying the rendering mechanism and format. */
BOOL         rc;         /* Validity indicator. */

rc = DrgVerifyNativeRMF(pDragitem, pRMF);
```

DrgVerifyNativeRMF Parameter - pDragitem

pDragitem (**PDRAGITEM**) - input
Pointer to the **DRAGITEM** structure. whose native rendering mechanism and format are to be verified.

DrgVerifyNativeRMF Parameter - pRMF

pRMF (**PSZ**) - input
A string specifying the rendering mechanism and format.

The string is of the form:

mechfmt[,mechfmt,mechfmt,...]

where mechfmt can be in either of these formats:

- <mechanism(1),format(1)>
- (mechanism(1)[,mechanism(n)...]), (format(1)[,format(n)...])

DrgVerifyNativeRMF Return Value - rc

rc (**BOOL**) - returns
Validity indicator.

TRUE	Successful completion.
FALSE	Error occurred.

DrgVerifyNativeRMF - Parameters

pDragitem ([PDRAGITEM](#)) - input
Pointer to the [DRAGITEM](#) structure. whose native rendering mechanism and format are to be verified.

pRMF ([PSZ](#)) - input
A string specifying the rendering mechanism and format.

The string is of the form:

```
mechfmt [ ,mechfmt ,mechfmt , . . . ]
```

where mechfmt can be in either of these formats:

- <mechanism(1),format(1)>
- (mechanism(1)[,mechanism(n)...]), (format(1)[,format(n)...])

rc ([BOOL](#)) - returns
Validity indicator.

TRUE	Successful completion.
FALSE	Error occurred.

DrgVerifyNativeRMF - Remarks

This function determines if the native rendering mechanism and format of a dragged object are understood by the target.

If TRUE is returned, the target may be able to carry out the action indicated by the direct manipulation itself, or it can select the native rendering mechanism and format as those to be used for the data exchange.

DrgVerifyRMF

DrgVerifyRMF - Syntax

This function determines if a given rendering mechanism and format are supported for a dragged object.

```

#define INCL_WINSTDDRAG
#include <os2.h>

```

```
PDRAGITEM    pDragitem; /* Pointer to the DRAGITEM structure whose native rendering mechanism and format are
PSZ           pMech;    /* String specifying the rendering mechanism to search for. */
PSZ           pFormat;  /* String specifying the rendering format to search for. */
BOOL          rc;       /* Validity indicator. */

rc = DrgVerifyRMF(pDragitem, pMech, pFormat);
```

DrgVerifyRMF Parameter - pDragitem

pDragitem (**PDRAGITEM**) - input
Pointer to the **DRAGITEM** structure whose native rendering mechanism and format are to be validated.

DrgVerifyRMF Parameter - pMech

pMech (**PSZ**) - input
String specifying the rendering mechanism to search for.

NULL will match any mechanism.

DrgVerifyRMF Parameter - pFormat

pFormat (**PSZ**) - input
String specifying the rendering format to search for.

NULL will match any format.

DrgVerifyRMF Return Value - rc

rc (**BOOL**) - returns
Validity indicator.

TRUE	Successful completion.
FALSE	Error occurred.

DrgVerifyRMF - Parameters

pDragitem ([PDRAGITEM](#)) - input
Pointer to the [DRAGITEM](#) structure whose native rendering mechanism and format are to be validated.

pMech ([PSZ](#)) - input
String specifying the rendering mechanism to search for.

NULL will match any mechanism.

pFormat ([PSZ](#)) - input
String specifying the rendering format to search for.

NULL will match any format.

rc ([BOOL](#)) - returns
Validity indicator.

TRUE	Successful completion.
FALSE	Error occurred.

DrgVerifyRMF - Remarks

This function determines if a given rendering mechanism and format ordered pair are represented in the set of valid pairs specified by */strRMF* for the dragged object.

DrgVerifyTrueType

DrgVerifyTrueType - Syntax

This function determines if the true type of a dragged object matches an application-supplied type string.

```
#define INCL_WINSTDDRAG
#include <os2.h>

PDRAGITEM    pDragitem; /* Pointer to the DRAGITEM structure whose true type is to be verified. */
PSZ          pType;     /* String specifying a type. */
BOOL         rc;        /* Validity indicator. */

rc = DrgVerifyTrueType(pDragitem, pType);
```

DrgVerifyTrueType Parameter - pDragitem

pDragitem ([PDRAGITEM](#)) - input

Pointer to the [DRAGITEM](#) structure whose true type is to be verified.

DrgVerifyTrueType Parameter - pType

pType ([PSZ](#)) - input

String specifying a type.

This string is in the format:

```
type[ , type... ]
```

DrgVerifyTrueType Return Value - rc

rc (**BOOL**) - returns
Validity indicator.

TRUE	Successful completion.
FALSE	Error occurred.

DrgVerifyTrueType - Parameters

pDragitem (**PDRAGITEM**) - input
Pointer to the **DRAGITEM** structure whose true type is to be verified.

pType (**PSZ**) - input
String specifying a type.

This string is in the format:

```
type[ , type... ]
```

rc (**BOOL**) - returns
Validity indicator.

TRUE	Successful completion.
FALSE	Error occurred.

DrgVerifyTrueType - Remarks

If an item in the string pointed to by *pType* matches the first type in the string associated with *hstrType* in the **DRAGITEM** structure, TRUE is returned.

A target application uses this function to determine if it supports the true type of a dragged object. If the application does not support the true type, it can either disallow a drop or change its default operation. If the default operation is a move, the drop should be disallowed, or the operation changed to a copy to prevent any loss of data for the object.

DrgVerifyType - Example Code

This example verifies whether a given type is present in the list of types defined for a drag object.

```
#define INCL_WINSTDDRAG /* Direct Manipulation (Drag) Functions */
#include <OS2.H>
```

```
BOOL    fValid;
```

```

DRAGITEM Dragitem;          /* DRAGITEM structure whose hstrType is */
                             /* to be verified */
char pszType[] = DRT_EXE;   /* A string specifying the types to */
                             /* search for */

fValid = DrgVerifyType(&Dragitem, pszType);

DrgVerifyTypeSet

DrgVerifyTypeSet - Syntax

This function returns the intersection of the contents of the string associated with the type-string handle for an object and an application-specified type string.

```

#define INCL_WINSTDDRAG
#include <os2.h>

PDRAGITEM    pDragitem; /* Pointer to the DRAGITEM structure whose hstrType is to be verified. */
PSZ          pType;     /* String specifying the types to search for. */
ULONG        cbBuflen;  /* Size of the return buffer. */
PSZ          pBuffer;   /* Buffer where the intersection string is returned. */
BOOL         rc;        /* Match indicator. */

rc = DrgVerifyTypeSet(pDragitem, pType, cbBuflen,
                     pBuffer);

```

DrgVerifyTypeSet Parameter - pDragitem

pDragitem ([PDRAGITEM](#)) - input
 Pointer to the [DRAGITEM](#) structure whose *hstrType* is to be verified.

DrgVerifyTypeSet Parameter - pType

pType (PSZ) - input
String specifying the types to search for.

This string is in the format:

type[, type...]

DrgVerifyTypeSet Parameter - cbBuflen

cbBuflen (ULONG) - input
Size of the return buffer.

The buffer should be at least one byte longer than the length of the string pointed to by *pType*. Must be > 0.

DrgVerifyTypeSet Parameter - pBuffer

pBuffer (PSZ) - output
Buffer where the intersection string is returned.

DrgVerifyTypeSet Return Value - rc

rc (BOOL) - returns
Match indicator.

TRUE Successful completion.
FALSE Error occurred.

DrgVerifyTypeSet - Parameters

pDragitem (PDRAGITEM) - input

Pointer to the [DRAGITEM](#) structure whose *hstrType* is to be verified.

pType ([PSZ](#)) - input
String specifying the types to search for.

This string is in the format:

```
type[ , type... ]
```

cbBuflen ([ULONG](#)) - input
Size of the return buffer.

The buffer should be at least one byte longer than the length of the string pointed to by *pType*. Must be > 0.

pBuffer ([PSZ](#)) - output
Buffer where the intersection string is returned.

rc ([BOOL](#)) - returns
Match indicator.

TRUE	Successful completion.
FALSE	Error occurred.

DrgVerifyTypeSet - Remarks

If at least one of the types specified by *pType* is present in *hstrType* in the [DRAGITEM](#) structure, TRUE is returned.

DrgVerifyTypeSet - Example Code

In this example, the DrgVerifyTypeSet function is used to determine whether DRT_TEXT is among the types associated with the object. If it is, the drop is accepted.

```
#define INCL_WINSTDDRAG /* Direct Manipulation (Drag) Functions */
#include <OS2.H>
#include <stdio.h>
BOOL flResult;
DRAGITEM pditem;
char szBuffer[32];

case DM_DRAGOVER:

    flResult = DrgVerifyTypeSet(&pditem,
                                DRT_TEXT,
```

```

        sizeof(szBuffer),
        szBuffer);

flResult = strcmp(szBuffer,DRT_TEXT);

/*****
/* See if the object is an OS/2 file as well as being of text */
/* format. AND result flag with previous result flag to get */
/* the "effective" return code. */
*****/

flResult = DrgVerifyRMF(&pditem,"DRM_OS2FILE","DRF_TEXT");

/*****
/* See if DRT_TEXT is the true type of the object */
*****/

flResult = DrgVerifyTrueType(&pditem,"DRF_TEXT");

if(!flResult)

/*****
/* Inform the application that you will accept the drop */
*****/

return(MRFROM2SHORT(DOR_DROP, DO_COPY));
break;

```

Dynamic Data Formatting Functions

The Information Presentation Facility (IPF) manages online, context-sensitive help information. Dynamic Data Formatting (DDF) is used for displaying dynamic help information. This section contains the DDF functions used to accomplish Dynamic Data Formatting.

DdfBeginList

DdfBeginList - Syntax

This function begins a definition list in the DDF buffer; it corresponds to the **:dl.** (definition list) tag.

```

#define INCL_DDF
#include <os2.h>

HDDF      hddf;          /* Handle to DDF returned by DdfInitialize. */
ULONG     ulWidthDT;     /* Width of the definition term. */
ULONG     fBreakType;    /* Type of line break to use. */
ULONG     fSpacing;      /* Spacing between definitions. */
BOOL      rc;            /* Success indicator. */

rc = DdfBeginList(hddf, ulWidthDT, fBreakType,
                  fSpacing);

```

DdfBeginList Parameter - hddf

hddf (**HDDF**) - input
Handle to DDF returned by [DdfInitialize](#).

DdfBeginList Parameter - ulWidthDT

ulWidthDT (**ULONG**) - input
Width of the definition term.

DdfBeginList Parameter - fBreakType

fBreakType (**ULONG**) - input
Type of line break to use.

The following constants may be specified:

HMBT_ALL	Start all definition descriptions on the next line, regardless of the actual lengths of definition terms.
HMBT_FIT	Start definition description on the next line only when the definition term is longer than the width specified.
HMBT_NONE	Do not start the definition description on the next line, even when the definition term is longer than the width specified.

DdfBeginList Parameter - fSpacing

fSpacing (**ULONG**) - input

Spacing between definitions.

Only the following constants may be specified:

HMLS_SINGLELINE

Do not insert a blank line between each definition description and the next definition term.

HMLS_DOUBLELINE

Insert a blank line between each definition description and the next definition term.

DdfBeginList Return Value - rc

rc (**BOOL**) - returns

Success indicator.

TRUE

Successful completion

FALSE

Error occurred.

DdfBeginList - Parameters

hddf (**HDDF**) - input

Handle to DDF returned by [DdfInitialize](#).

ulWidthDT (**ULONG**) - input

Width of the definition term.

fBreakType (**ULONG**) - input

Type of line break to use.

The following constants may be specified:

HMBT_ALL

Start all definition descriptions on the next line, regardless of the actual lengths of definition terms.

HMBT_FIT

Start definition description on the next line only when the definition term is longer than the width specified.

HMBT_NONE

Do not start the definition description on the next line, even when the definition term is longer than the width specified.

fSpacing (**ULONG**) - input

Spacing between definitions.

Only the following constants may be specified:

HMLS_SINGLELINE

Do not insert a blank line between each definition description and the next definition term.

HMLS_DOUBLELINE

Insert a blank line between each definition description and the next definition term.

rc (**BOOL**) - returns

Success indicator.

TRUE

FALSE	Successful completion
	Error occurred.

DdfBeginList - Remarks

Once this function has been called, use of any DDF function other than [DdfListItem](#), [DdfSetColor](#), and [DdfEndList](#) may produce unpredictable results.

DdfBeginList - Errors

Possible returns from [WinGetLastError](#)

HMERR_DDF_MEMORY (0x3001)
Not enough memory is available.

HMERR_DDF_LIST_UNCLOSED (0x3007)
An attempt was made to nest a list.

HMERR_DDF_LIST_BREAKTYPE (0x3009)
The value of BreakType is not valid.

HMERR_DDF_LIST_SPACING (0x300A)
The value for Spacing is not valid.

DdfBitmap

DdfBitmap - Syntax

This function places a reference to a bit map in the DDF buffer.

```
#define INCL_DDF
#include <os2.h>

HDDF      hddf;      /* Handle to DDF returned by DdfInitialize. */
HBITMAP    hbm;      /* Standard Presentation Manager bit map handle. */
ULONG      fAlign;    /* Text justification flag. */
BOOL       rc;        /* Success indicator. */

rc = DdfBitmap(hddf, hbm, fAlign);
```

DdfBitmap Parameter - hddf

hddf ([HDDF](#)) - input
Handle to DDF returned by [DdfInitialize](#).

DdfBitmap Parameter - hbm

hbm ([HBITMAP](#)) - input
Standard Presentation Manager bit map handle.

DdfBitmap Parameter - fAlign

fAlign (ULONG) - input
Text justification flag.

Any of the following values can be specified:

- | | |
|------------|---|
| ART_LEFT | Left-justify the bit map. |
| ART_RIGHT | Right-justify the bit map. |
| ART_CENTER | Center the bit map. |
| ART_RUNIN | Allow the bit map to be reflowed with text. |

DdfBitmap Return Value - rc

rc (BOOL) - returns
Success indicator.

- | | |
|-------|-----------------------|
| TRUE | Successful completion |
| FALSE | Error occurred. |

DdfBitmap - Parameters

hddf (HDDF) - input
Handle to DDF returned by [DdfInitialize](#).

hbm (HBITMAP) - input
Standard Presentation Manager bit map handle.

fAlign (ULONG) - input
Text justification flag.

Any of the following values can be specified:

- | | |
|------------|---|
| ART_LEFT | Left-justify the bit map. |
| ART_RIGHT | Right-justify the bit map. |
| ART_CENTER | Center the bit map. |
| ART_RUNIN | Allow the bit map to be reflowed with text. |

rc (BOOL) - returns
Success indicator.

- | | |
|-------|-----------------------|
| TRUE | Successful completion |
| FALSE | Error occurred. |

DdfBitmap - Remarks

The handle to the presentation space in which the bit map was created cannot be freed by the application while the panel is displayed.

Note: There is a (3-byte + size of [HBITMAP](#) structure). ESC code overhead in the DDF internal buffer for this function. There is a 1-byte ESC code overhead required for the *Align* flag.

DdfBitmap - Errors

Possible returns from [WinGetLastError](#)

HMERR_DDF_MEMORY (0x3001)
Not enough memory is available.

HMERR_DDF_ALIGN_TYPE (0x3002)
The alignment type is not valid.

DdfHyperText

DdfHyperText - Syntax

This function defines a hypertext link to another panel, which is equal to a link of reftype=hd. Links to footnotes, launch links and links to external databases are not supported.

```

#define INCL_DDF
#include <os2.h>

HDDF      hddf;          /* Handle to DDF returned by DdfInitialize. */
PCSZ      pszText;        /* Hypertext phrase. */
PCSZ      pszReference;    /* Pointer to a string containing the link reference. */
ULONG     fReferenceType; /* Reference Type. */
BOOL      rc;             /* Success indicator. */

rc = DdfHyperText(hddf, pszText, pszReference,
                  fReferenceType);

```

DdfHyperText Parameter - hddf

hddf (**HDDF**) - input
Handle to DDF returned by [DdfInitialize](#).

DdfHyperText Parameter - pszText

pszText (**PCSZ**) - input
Hypertext phrase.

DdfHyperText Parameter - pszReference

pszReference (**PCSZ**) - input
Pointer to a string containing the link reference.

The value of this parameter depends on the value of *fReferenceType*.

If *fReferenceType* is **REFERENCE_BY_RES**
pszReference must contain a pointer to a numeric string containing the res number; otherwise it will default to a res number of zero. Valid values are 1 - 64000; all other values are reserved.

If *fReferenceType* is **REFERENCE_BY_ID**
pszReference must contain a pointer to a string containing the alphanumeric identifier of the destination panel.

DdfHyperText Parameter - fReferenceType

fReferenceType (**ULONG**) - input
Reference Type.

This parameter specifies whether you are linking via a resource identifier (res number) or via an alphanumeric identifier.

REFERENCE_BY_RES
To link via a resource identifier.

REFERENCE_BY_ID
To link via an alphanumeric identifier.

DdfHyperText Return Value - rc

rc (**BOOL**) - returns

Success indicator.

TRUE

Successful completion

FALSE

Error occurred.

DdfHyperText - Parameters

hddf ([HDDF](#)) - input

Handle to DDF returned by [DdfInitialize](#).

pszText ([PCSZ](#)) - input

Hypertext phrase.

pszReference ([PCSZ](#)) - input

Pointer to a string containing the link reference.

The value of this parameter depends on the value of *fReferenceType*.

If *fReferenceType* is `REFERENCE_BY_RES`

pszReference must contain a pointer to a numeric string containing the res number; otherwise it will default to a res number of zero. Valid values are 1 - 64000; all other values are reserved.

If *fReferenceType* is `REFERENCE_BY_ID`

pszReference must contain a pointer to a string containing the alphanumeric identifier of the destination panel.

fReferenceType ([ULONG](#)) - input

Reference Type.

This parameter specifies whether you are linking via a resource identifier (res number) or via an alphanumeric identifier.

`REFERENCE_BY_RES`

To link via a resource identifier.

`REFERENCE_BY_ID`

To link via an alphanumeric identifier.

rc ([BOOL](#)) - returns

Success indicator.

TRUE

Successful completion

FALSE

Error occurred.

DdfHyperText - Remarks

There is a 3-byte ESC code overhead in the DDF internal buffer for each word in the text buffer. There is a 1-byte ESC code overhead for each blank and for each newline character. If *fReferenceType* is `REFERENCE_BY_ID`, then there is a (3-byte + Reference length) ESC code overhead. For a *fReferenceType* of `REFERENCE_BY_RES`, the overhead is 5 bytes. Finally, there is a 3-byte ESC code overhead that is required for ending the hypertext link.

DdfHyperText - Errors

Possible returns from [WinGetLastError](#)

HMERR_DDF_MEMORY (0x3001)
Not enough memory is available.

HMERR_DDF_REFTYPE (0x3006)
The reference type is not valid.

DdfInform

DdfInform - Syntax

This function defines a hypertext inform link, which sends an HM_INFORM message to the application with a **res=** attribute. It also corresponds to the link tag with reftype=inform.

```

#define INCL_DDF
#include <os2.h>

HDDF      hddf;          /* Handle to DDF returned by DdfInitialize. */
PCSZ      pszText;       /* Hypertext phrase. */
ULONG     resInformNumber; /* Res number associated with this hypertext field. */
BOOL      rc;            /* Success indicator. */

rc = DdfInform(hddf, pszText, resInformNumber);

```

DdfInform Parameter - hddf

hddf ([HDDF](#)) - input
Handle to DDF returned by [DdfInitialize](#).

DdfInform Parameter - pszText

pszText ([PCSZ](#)) - input
Hypertext phrase.

DdfInform Parameter - resInformNumber

resInformNumber ([ULONG](#)) - input
Res number associated with this hypertext field.

Possible values are 1 to 64000; all other values are reserved.

DdfInform Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

DdfInform - Parameters

hddf ([HDDF](#)) - input

DdfInform - Example Code

After initializing a DDF buffer with [DdfInitialize](#), the example uses [DdfInform](#) to create a hypertext inform link with another resource (corresponds to the IPF :link. tag with reftype=inform). For a more detailed example and discussion of initializing DDF, see the [DdfInitialize](#) sample.

```
#define INCL_WINWINDOWMGR            /* General window management    */
#define INCL_WINMESSAGEGR           /* Message management           */
#define INCL_DDF                    /* Dynamic Data Facility        */
#include <os2.h>
#include <pmhelp.h>

PSZ     Text = "This text is a HYPERTEXT message.\n"; /* hypertext string */
MRESULT WindowProc( HWND hwnd, ULONG ulMsg, MPARAM mp1, MPARAM mp2 )
{
    HWND    hwndParent;
    HWND    hwndInstance;
    HDDF    hDdf;                   /* DDF handle                   */

    switch( ulMsg )
    {
        case HM_QUERY_DDF_DATA:
            /* get the help instance */
            hwndParent = WinQueryWindow( hwnd, QW_PARENT );
```

```

        hwndParent = WinQueryWindow( hwndParent, QW_PARENT );
        hwndInstance = (HWND)WinSendMsg( hwndParent, HM_QUERY,
                                          MPFROMSHORT( HMQW_INSTANCE ), NULL );

/* Allocate 1K Buffer (default) */
hDdf = DdfInitialize(
        hwndInstance, /* Handle of help instance */
        0L,           /* Default buffer size */
        0L,           /* Default increment */
        );

if (hDdf == NULLHANDLE) /* Check return code */
{
    return (MRESULT)FALSE;
}

/* create hypertext inform link with resource 1 */
if (!DdfInform(hDdf, (PSZ)Text, 1L))
{
    return (MRESULT)FALSE;
}

return (MRESULT)hDdf;
}
}

DdfInitialize

DdfInitialize - Syntax

This function initializes the IPF internal structures for dynamic data formatting and returns a DDF handle. The application uses this handle to refer to a particular DDF panel.

```

#define INCL_DDF
#include <os2.h>

HWND    hwndHelpInstance; /* Handle of a help instance. */
ULONG   cbBuffer;         /* Initial length of internal buffer. */
ULONG   ulIncrement;      /* Amount by which to increment the buffer size, if necessary. */
HDDF    hddf;             /* Handle to DDF. */

hddf = DdfInitialize(hwndHelpInstance, cbBuffer,
                     ulIncrement);

```

DdfInitialize Parameter - hwndHelpInstance

hwndHelpInstance ([HWND](#)) - input
Handle of a help instance.

DdfInitialize Parameter - cbBuffer

cbBuffer ([ULONG](#)) - input
Initial length of internal buffer.

Initial length of internal buffer where DDF information is to be stored. If this field is 0L, a default value of 1K is defined. The maximum value is 61 440 bytes (60KB).

DdfInitialize Parameter - ullIncrement

ullIncrement ([ULONG](#)) - input
Amount by which to increment the buffer size, if necessary.

If this field is NULL, a default value of 256 bytes is defined. The maximum value is 60KB.

DdfInitialize Return Value - hddf

hddf ([HDDF](#)) - returns
Handle to DDF.

A handle to DDF is returned if initialization was successful. Otherwise, the value returned is NULL, indicating that an error has occurred because of insufficient memory or incorrect instance.

DdfInitialize - Parameters

hwndHelpInstance ([HWND](#)) - input
Handle of a help instance.

cbBuffer ([ULONG](#)) - input

Initial length of internal buffer.

Initial length of internal buffer where DDF information is to be stored. If this field is 0L, a default value of 1K is defined. The maximum value is 61 440 bytes (60KB).

ullIncrement ([ULONG](#)) - input

Amount by which to increment the buffer size, if necessary.

If this field is NULL, a default value of 256 bytes is defined. The maximum value is 60KB.

hddf ([HDDF](#)) - returns

Handle to DDF.

A handle to DDF is returned if initialization was successful. Otherwise, the value returned is NULL, indicating that an error has occurred because of insufficient memory or incorrect instance.

DdfInitialize - Remarks

At initialization, the default for dynamic data display is that text aligned on the left, and formatting is turned on.

DdfInitialize - Example Code

This example shows how to initialize and use the Dynamic Data Facility for displaying an online document. Two functions are defined: the first, `SampleObj`, creates a window that will display the online information and specifies the second function, `SampleWindowProc`, as the corresponding window procedure. These two functions are compiled into a DLL and exported, so that IPF can invoke them when it encounters the `:ddf` and `:acviewport` tags during execution. The `:acviewport` tag will specify the DLL name and the `SampleObj` function; when IPF calls `SampleObj`, it initializes an application-controlled window with `SampleWindowProc` as the window procedure and returns the window handle. Later, when IPF encounters the `:ddf` tag, it will send `SampleWindowProc` an `HM_QUERY_DDF_DATA` message. At this point, before calling any of the DDF API, `DdfInitialize` must first be called to initiate a DDF buffer, after which the other DDF API can be called to display the online information.

```
#define INCL_WINWINDOWMGR      /* General window management */
#define INCL_WINMESSAGEGR     /* Message management */
#define INCL_WINDIALOGS       /* Dialog boxes */
#define INCL_DDF              /* Dynamic Data Facility */
```

```

#define INCL_32

DdfListItem

DdfListItem - Syntax

This function inserts a definition list entry in the DDF buffer; it corresponds to a combination of the **:dt.** (definition term) and **:dd.** (definition define) tags.

```

#define INCL_DDF
#include <os2.h>

HDDF    hddf;           /* Handle to DDF returned by DdfInitialize. */
PCSZ    pszTerm;        /* Term portion of the definition list entry. */
PCSZ    pszDescription; /* Description portion of the definition list entry. */
BOOL    rc;             /* Success indicator. */

rc = DdfListItem(hddf, pszTerm, pszDescription);

```

DdfListItem Parameter - hddf

hddf ([HDDF](#)) - input
Handle to DDF returned by [DdfInitialize](#).

DdfListItem Parameter - pszTerm

pszTerm ([PCSZ](#)) - input
Term portion of the definition list entry.

DdfListItem Parameter - pszDescription

pszDescription ([PCSZ](#)) - input
Description portion of the definition list entry.

Note: There is a 3-byte ESC code overhead in the DDF internal buffer for each word in both the term and the description. There is a 1-byte ESC code overhead for each blank and for each new-line character. For each list item, there is a 5-byte ESC code overhead for the margin alignment.

DdfListItem Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

DdfListItem - Parameters

hddf ([HDDF](#)) - input
Handle to DDF returned by [DdfInitialize](#).

pszTerm ([PCSZ](#)) - input
Term portion of the definition list entry.

pszDescription ([PCSZ](#)) - input
Description portion of the definition list entry.

Note: There is a 3-byte ESC code overhead in the DDF internal buffer for each word in both the term and the description. There is a 1-byte ESC code overhead for each blank and for each new-line character. For each list item, there is a 5-byte ESC code overhead for the margin alignment.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

DdfListItem - Remarks

The handle to the presentation space in which the bit map was created cannot be freed by the application while the panel is displayed.

Note: There is a (3-byte + size of HBITMAP structure) ESC code overhead in the DDF internal buffer for this function. There is a 1-byte ESC code overhead required for the Align flag.

DdfListItem - Errors

Possible returns from [WinGetLastError](#)

HMERR_DDF_MEMORY (0x3001)
Not enough memory is available.

HMERR_DDF_LIST_UNINITIALIZED (0x3008)
No definition list has been initialized by [DdfBeginList](#).

DdfMetafile

DdfMetafile - Syntax

This function places a reference to a metafile into the DDF buffer.

```
#define INCL_DDF  
#include <os2.h>  
  
HDDF      hddf;      /* Handle to DDF returned by DdfInitialize. */  
HMF      hmf;        /* The handle of the metafile to display. */  
PRECTL    prclRect;   /* Size of the rectangle. */  
BOOL      rc;         /* Success indicator. */  
  
rc = DdfMetafile(hddf, hmf, prclRect);
```

DdfMetafile Parameter - hddf

hddf (**HDDF**) - input

Handle to DDF returned by [DdfInitialize](#).

DdfMetafile Parameter - hmf

hmf ([HMF](#)) - input
The handle of the metafile to display.

DdfMetafile Parameter - prclRect

prclRect ([PRECTL](#)) - input
Size of the rectangle.

If not NULL, contains the size of the rectangle in which the metafile will be displayed. The aspect ratio of the metafile is adjusted to fit this rectangle.

DdfMetafile Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

DdfMetafile - Parameters

hddf ([HDDF](#)) - input
Handle to DDF returned by [DdfInitialize](#).

hmf ([HMF](#)) - input
The handle of the metafile to display.

prclRect ([PRECTL](#)) - input
Size of the rectangle.

If not NULL, contains the size of the rectangle in which the metafile will be displayed. The aspect ratio of the metafile is adjusted to fit this rectangle.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

DdfMetafile - Remarks

There is a 3-byte ESC code overhead in the DDF internal buffer for this function. There is also a (MetaFilename length) overhead. Finally, the *prcRect* variable requires an additional 16 bytes of overhead in the DDF internal buffer.

DdfMetafile - Errors

Possible returns from [WinGetLastError](#)

HMERR_DDF_MEMORY (0x3001)
Not enough memory is available.

DdfPara

DdfPara - Syntax

This function creates a paragraph within the DDF buffer. It corresponds to the **:p.** tag. This function places a reference to a bit map in the DDF buffer.

```
#define INCL_DDF
#include <os2.h>

HDDF    hddf; /* Handle to DDF returned by DdfInitialize. */
BOOL    rc;    /* Success indicator. */

rc = DdfPara(hddf);
```

DdfPara Parameter - hddf

hddf (**HDDF**) - input
Handle to DDF returned by [DdfInitialize](#).

DdfPara Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

DdfPara - Parameters

hddf (**HDDF**) - input
Handle to DDF returned by [DdfInitialize](#).

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

DdfPara - Remarks

There is a 1-byte ESC code overhead in the DDF internal buffer for this function.

DdfPara - Errors

Possible returns from [WinGetLastError](#)

HMERR_DDF_MEMORY (0x3001)
Not enough memory is available.

DdfSetColor

DdfSetColor - Syntax

This function sets the background and foreground colors of the displayed text.

```
#define INCL_DDF
#include <os2.h>

HDDF      hddf;          /* Handle to DDF returned by DdfInitialize. */
COLOR     fBackColor;    /* Specifies the desired background color. */
COLOR     fForeColor;    /* Specifies the desired foreground color. */
BOOL      rc;            /* Success indicator. */

rc = DdfSetColor(hddf, fBackColor, fForeColor);
```

DdfSetColor Parameter - hddf

hddf ([HDDF](#)) - input
Handle to DDF returned by [DdfInitialize](#).

DdfSetColor Parameter - fBackColor

fBackColor ([COLOR](#)) - input
Specifies the desired background color.

DdfSetColor Parameter - fForeColor

fForeColor ([COLOR](#)) - input
Specifies the desired foreground color.

The following color value constants may be used for the foreground and background colors:

- CLR_DEFAULT - used to set IPF default text color
- CLR_BLACK
- CLR_BLUE
- CLR_RED
- CLR_PINK

CLR_GREEN
CLR_CYAN
CLR_YELLOW
CLR_BROWN
CLR_DARKGRAY
CLR_DARKBLUE
CLR_DARKRED
CLR_DARKPINK
CLR_DARKGREEN
CLR_DARKCYAN
CLR_PALEGGRAY

DdfSetColor Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

DdfSetColor - Parameters

hddf (**HDDF**) - input
Handle to DDF returned by [DdfInitialize](#).

fBackColor (**COLOR**) - input
Specifies the desired background color.

fForeColor (**COLOR**) - input
Specifies the desired foreground color.

The following color value constants may be used for the foreground and background colors:

CLR_DEFAULT - used to set IPF default text color
CLR_BLACK
CLR_BLUE
CLR_RED
CLR_PINK
CLR_GREEN
CLR_CYAN
CLR_YELLOW
CLR_BROWN
CLR_DARKGRAY
CLR_DARKBLUE
CLR_DARKRED
CLR_DARKPINK
CLR_DARKGREEN
CLR_DARKCYAN
CLR_PALEGGRAY

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	

Error occurred.

DdfSetColor - Remarks

There is a 4-byte ESC code overhead in the DDF internal buffer for the foreground color, and a 4-byte overhead for the background color, with this function.

DdfSetColor - Errors

Possible returns from [WinGetLastError](#)

HMERR_DDF_MEMORY (0x3001)
Not enough memory is available.

HMERR_DDF_BACKCOLOR (0x3003)
The background color is not valid.

HMERR_DDF_FORECOLOR (0x3004)
The foreground color is not valid.

DdfSetFont

DdfSetFont - Syntax

This function specifies a text font in the DDF buffer.

```
#define INCL_DDF
#include <os2.h>

HDDF      hddf;          /* Handle to DDF returned by DdfInitialize. */
PCSZ      pszFaceName;   /* Pointer to font name. */
ULONG     ulWidth;       /* Font width in points. */
ULONG     ulHeight;      /* Font height in points. */
BOOL      rc;            /* Success indicator. */

rc = DdfSetFont(hddf, pszFaceName, ulWidth,
               ulHeight);
```

DdfSetFont Parameter - hddf

hddf ([HDDF](#)) - input
Handle to DDF returned by [DdfInitialize](#).

DdfSetFont Parameter - pszFaceName

pszFaceName ([PCSZ](#)) - input
Pointer to font name.

This parameter can be specified in two ways:

- An ASCIIZ string specifying the font name.
 - NULL or "default" to specify the default font.
-

DdfSetFont Parameter - ulWidth

ulWidth ([ULONG](#)) - input
Font width in points.

A point is approximately 1/72 of an inch.

DdfSetFont Parameter - ulHeight

ulHeight ([ULONG](#)) - input
Font height in points.

DdfSetFont Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

This function specifies a text font style in the DDF buffer.

```
#define INCL_DDF
#include <os2.h>

HDDF    hddf;          /* Handle to DDF returned by DdfInitialize. */
ULONG    fFontStyle;    /* Font style flag. */
BOOL     rc;            /* Success indicator. */

rc = DdfSetFontStyle(hddf, fFontStyle);
```

DdfSetFontStyle Parameter - hddf

hddf (**HDDF**) - input
Handle to DDF returned by [DdfInitialize](#).

DdfSetFontStyle Parameter - fFontStyle

fFontStyle (**ULONG**) - input
Font style flag.

A NULL value for this parameter will set the font-style back to the default. Any of the following values can be specified:

FM_SEL_ITALIC
FM_SEL_BOLD
FM_SEL_UNDERSCORE

These values can be "ORed" together to combine different font styles.

Note: There is a 4-byte ESC code overhead in the DDF internal buffer for *fFontStyle*.

DdfSetFontStyle Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE
Successful completion.
FALSE
Error occurred.

DdfSetFontStyle - Parameters

hddf ([HDDF](#)) - input
Handle to DDF returned by [DdfInitialize](#).

fFontStyle ([ULONG](#)) - input
Font style flag.

A NULL value for this parameter will set the font-style back to the default. Any of the following values can be specified:

FM_SEL_ITALIC
FM_SEL_BOLD
FM_SEL_UNDERSCORE

These values can be "ORed" together to combine different font styles.

Note: There is a 4-byte ESC code overhead in the DDF internal buffer for *fFontStyle*.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion.
FALSE	Error occurred.

DdfSetFontStyle - Errors

Possible returns from [WinGetLastError](#)

HMERR_DDF_MEMORY (0x3001)
Not enough memory is available.

HMERR_DDF_FONTSTYLE (0x3005)
The font style is not valid.

DdfSetFontStyle - Example Code

After initializing a DDF buffer with [DdfInitialize](#), the example uses DdfPara to start a new paragraph, DdfSetFont and DdfSetFontStyle to have the text displayed in a large, bold Courier font, DdfSetColor to change the text color, and DdfText to place text in the buffer. For a more detailed example and discussion of initializing DDF, see the [DdfInitialize](#) sample.

DdfSetFormat

DdfSetFormat - Syntax

This function is used to turn formatting off or on. It corresponds to the **:lines.** tag.

```
#define INCL_DDF
#include <os2.h>

HDDF    hddf;          /* Handle to DDF returned by DdfInitialize. */
ULONG   fFormatType;   /* Formatting-activation flag. */
BOOL    rc;            /* Success indicator. */

rc = DdfSetFormat(hddf, fFormatType);
```

DdfSetFormat Parameter - hddf

hddf ([HDDF](#)) - input

Handle to DDF returned by [DdfInitialize](#).

DdfSetFormat Parameter - fFormatType

fFormatType ([ULONG](#)) - input

Formatting-activation flag.

Only the following constants may be used in this parameter:

- | | |
|-------|----------------------|
| TRUE | Turn formatting on. |
| FALSE | Turn formatting off. |

DdfSetFormat Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

- | | |
|-------|-----------------------|
| TRUE | Successful completion |
| FALSE | Error occurred. |

DdfSetFormat - Parameters

hddf ([HDDF](#)) - input
Handle to DDF returned by [DdfInitialize](#).

fFormatType ([ULONG](#)) - input
Formatting-activation flag.

Only the following constants may be used in this parameter:

- | | |
|-------|----------------------|
| TRUE | Turn formatting on. |
| FALSE | Turn formatting off. |

rc ([BOOL](#)) - returns
Success indicator.

- | | |
|-------|-----------------------|
| TRUE | Successful completion |
| FALSE | Error occurred. |

DdfSetFormat - Remarks

If formatting is ON, there is a 3-byte ESC code overhead in the DDF internal buffer for this function. Otherwise, there is a 4-byte ESC code overhead.

DdfSetFormat - Errors

Possible returns from [WinGetLastError](#)

HMERR_DDF_MEMORY (0x3001)
Not enough memory is available.

DdfSetTextAlign

DdfSetTextAlign - Syntax

This function defines whether left, center, or right text justification is to be used when text formatting is off.

```

#define INCL_DDF
#include <os2.h>

HDDF      hddf;      /* Handle to DDF returned by DdfInitialize. */
ULONG     fAlign;    /* Justification flag. */
BOOL      rc;        /* Success indicator. */

rc = DdfSetTextAlign(hddf, fAlign);

```

DdfSetTextAlign Parameter - hddf

hddf ([HDDF](#)) - input
Handle to DDF returned by [DdfInitialize](#).

DdfSetTextAlign Parameter - fAlign

fAlign ([ULONG](#)) - input
Justification flag.

Only the following constants may be used:

TA_LEFT	Left-justify text.
TA_RIGHT	Right-justify text.
TA_CENTER	Center text.

DdfSetTextAlign Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion.
FALSE	Error occurred.

DdfSetTextAlign - Parameters

hddf ([HDDF](#)) - input
Handle to DDF returned by [DdfInitialize](#).

fAlign ([ULONG](#)) - input
Justification flag.

Only the following constants may be used:

TA_LEFT	Left-justify text.
TA_RIGHT	

TA_CENTER	Right-justify text.
	Center text.
rc (BOOL) - returns	
	Success indicator.
TRUE	Successful completion.
FALSE	Error occurred.

DdfSetTextAlign - Remarks

It should be called before DdfSetFormat is called to turn off text formatting, and should not be called again until formatting is turned back on. Note that leading and trailing spaces are not stripped from the text as a result of this alignment.

DdfSetTextAlign - Errors

Possible returns from [WinGetLastError](#)

HMERR_DDF_ALIGN_TYPE (0x3002)
The alignment type is not valid.

DdfText

DdfText - Syntax

This function adds text to the DDF buffer.

```
#define INCL_DDF
#include <os2.h>

HDDF    hddf;    /* Handle to DDF returned by DdfInitialize. */
PCSZ    pszText; /* Pointer to the text buffer to be formatted. */
BOOL    rc;      /* Success indicator. */

rc = DdfText(hddf, pszText);
```

DdfText Parameter - hddf

hddf (**HDDF**) - input
Handle to DDF returned by [DdfInitialize](#).

DdfText Parameter - pszText

pszText (**PCSZ**) - input
Pointer to the text buffer to be formatted.

Note: There is a 3-byte ESC code overhead in the DDF internal buffer for each word in the text buffer. There is a 1-byte ESC code overhead for each blank and for each newline character.

DdfText Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion.
FALSE	

Error occurred.

DdfText - Parameters

hddf ([HDDF](#)) - input
Handle to DDF returned by [DdfInitialize](#).

pszText ([PCSZ](#)) - input
Pointer to the text buffer to be formatted.

Note: There is a 3-byte ESC code overhead in the DDF internal buffer for each word in the text buffer. There is a 1-byte ESC code overhead for each blank and for each newline character.

rc ([BOOL](#)) - returns

Hooks and Procedures

This section describes dialog procedures, window procedures, and hooks. It shows the input parameters and returns that the operating system expects an application to use in application procedures and that can be called by the operating system in response to certain events.

Procedures and hooks are application code that is called by the system in response to certain events.

The names and parameter lists of functions are contained in header files that are incorporated into the application when it is compiled. Their addresses are contained in .LIB files that are incorporated at link time.

The names of procedures and hooks are defined by the application, and their parameter lists are defined by the system. Function prototypes for these procedures and hooks are in PMWIN.H. The prototypes have sample names that can be changed by the programmer before they are inserted into the application source code.

The application passes the address of these procedures and hooks in the following ways:

Dialog procedures	During the WinLoadDlg, WinDlgBox, WinFileDlg, or WinFontDlg function
Window procedures	During the WinRegisterClass or WinSubclassWindow functions
Hooks	During the WinSetHook function
Thunks	During the WinSetClassThunkProc or WinSetWindowThunkProc functions.

Hook Functions

This section of the chapter describes the hook functions that the application can provide:

- [CheckMsgFilterHook](#)
 - [CodePageChangedHook](#)
 - [DestroyWindowHook](#)
 - [DialogProc](#)
 - [FindWordHook](#)
 - [FlushBufHook](#)
 - [HelpHook](#)

CheckMsgFilterHook

CheckMsgFilterHook - Syntax

This hook is called whenever [WinGetMsg](#), [WinWaitMsg](#), or [WinPeekMsg](#) are used to filter message identities.

```
#define INCL_WINHOOKS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
PQMSG    pQmsg;        /* Pointer to the QMSG structure of the message currently being reviewed. */
ULONG    usFirst;      /* First message identity specified on a call to the WinGetMsg, WinPeekMsg or WinWaitMsg f
ULONG    usLast;       /* Last message identity specified on a call to the WinGetMsg, WinPeekMsg or WinWaitMsg fun
ULONG    fOptions;     /* Message removal options. */
BOOL     rc;           /* Processing indicator. */

rc = CheckMsgFilterHook(hab, pQmsg, usFirst,
                        usLast, fOptions);
```

CheckMsgFilterHook Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

CheckMsgFilterHook Parameter - pQmsg

pQmsg ([PQMSG](#)) - input
Pointer to the [QMSG](#) structure of the message currently being reviewed.

CheckMsgFilterHook Parameter - usFirst

usFirst ([ULONG](#)) - input
First message identity specified on a call to the [WinGetMsg](#), [WinPeekMsg](#) or [WinWaitMsg](#) function.

CheckMsgFilterHook Parameter - usLast

usLast ([ULONG](#)) - input
Last message identity specified on a call to the [WinGetMsg](#), [WinPeekMsg](#) or [WinWaitMsg](#) function.

CheckMsgFilterHook Parameter - fOptions

fOptions ([ULONG](#)) - input
Message removal options.

PM_REMOVE Message is being removed from queue
PM_NOREMOVE Message is not being removed from queue.

CheckMsgFilterHook Return Value - rc

rc ([BOOL](#)) - returns
Processing indicator.

TRUE
The message is accepted by the filtering. Any further Check Message Filter Hooks in the chain are ignored, any filtering specified by the *uIfirst* and *uIfirst* parameters of the [WinGetMsg](#), [WinPeekMsg](#) or [WinWaitMsg](#) functions are ignored, and processing of the message continues.

A hook that always returns TRUE effectively switches off message filtering.

FALSE
The message is passed on to the next Check Message Filter Hook in the chain. If the end of the chain has been reached, the filtering specified by the *uIfirst* and *uIfirst* parameters of the [WinGetMsg](#), [WinPeekMsg](#) or [WinWaitMsg](#) functions is applied.

CheckMsgFilterHook - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

pQmsg ([PQMSG](#)) - input
Pointer to the [QMSG](#) structure of the message currently being reviewed.

usFirst ([ULONG](#)) - input
First message identity specified on a call to the [WinGetMsg](#), [WinPeekMsg](#) or [WinWaitMsg](#) function.

usLast ([ULONG](#)) - input
Last message identity specified on a call to the [WinGetMsg](#), [WinPeekMsg](#) or [WinWaitMsg](#) function.

fOptions ([ULONG](#)) - input
Message removal options.

PM_REMOVE Message is being removed from queue
PM_NOREMOVE Message is not being removed from queue.

rc ([BOOL](#)) - returns
Processing indicator.

TRUE

The message is accepted by the filtering. Any further Check Message Filter Hooks in the chain are ignored, any filtering specified by the *uIfirst* and *uIfast* parameters of the [WinGetMsg](#), [WinPeekMsg](#) or [WinWaitMsg](#) functions are ignored, and processing of the message continues.

A hook that always returns TRUE effectively switches off message filtering.

FALSE

The message is passed on to the next Check Message Filter Hook in the chain. If the end of the chain has been reached, the filtering specified by the *uIfirst* and *uIfast* parameters of the [WinGetMsg](#), [WinPeekMsg](#) or [WinWaitMsg](#) functions is applied.

CheckMsgFilterHook - Remarks

This hook enables an application to apply a very specific message filtering, for example, based on the values of message parameters.

This hook is called after window handle filtering and before message filtering. Window handle filtering is controlled by the *hwndFilter* parameter of the [WinGetMsg](#) or [WinPeekMsg](#) functions. Message filtering is controlled by the *uIfirst* and *uIfast* parameters of the [WinGetMsg](#), [WinPeekMsg](#) or [WinWaitMsg](#) functions.

This hook is called if the message passes window handle filtering and if non-null message filtering is specified. This means that, on entry to this hook:

- The *hwndFilter* parameter of the [WinGetMsg](#) or [WinPeekMsg](#) function is either NULLHANDLE or it specifies the window (or a parent of the window) referenced in the *pQmsg* structure.
- At least one of the *usFirst* and *usLast* parameters are nonzero.
- The field of the *pQmsg* structure might or might not lie inside the range specified by the *usFirst* and *usLast* parameters.

CodePageChangedHook

CodePageChangedHook - Syntax

This hook notifies that a message queue code page has been changed.

```
#define INCL_WINHOOKS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HMQ      hmq;          /* Message-queue handle. */
ULONG    usOldCodePage; /* Previous code page. */
ULONG    usNewCodePage; /* New code page. */

CodePageChangedHook(hmq, usOldCodePage, usNewCodePage);
```

CodePageChangedHook Parameter - hmq

hmq ([HMQ](#)) - input
Message-queue handle.

The handle of the message queue that is changing its code page.

CodePageChangedHook Parameter - usOldCodePage

usOldCodePage ([ULONG](#)) - input
Previous code page.

CodePageChangedHook Parameter - usNewCodePage

usNewCodePage ([ULONG](#)) - input
New code page.

CodePageChangedHook - Return Value

There is no return value for this hook.

CodePageChangedHook - Parameters

hmq ([HMQ](#)) - input

Message-queue handle.

The handle of the message queue that is changing its code page.

usOldCodePage ([ULONG](#)) - input
Previous code page.

usNewCodePage ([ULONG](#)) - input
New code page.

There is no return value for this hook.

CodePageChangedHook - Remarks

This hook is sent to all hooks chained under HK_CODEPAGECHANGED, regardless of the return value.

The new code page is set before this hook is called.

CodePageChangedHook - Topics

DestroyWindowHook

DestroyWindowHook - Syntax

This hook is called whenever a window is destroyed.

```
#define INCL_WINHOOKS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
HWND     hwnd;         /* The handle of the window being destroyed. */
ULONG    ulReserved;   /* Reserved. */
BOOL     rc;           /* Success indicator. */

rc = DestroyWindowHook(hab, hwnd, ulReserved);
```

DestroyWindowHook Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

DestroyWindowHook Parameter - hwnd

hwnd ([HWND](#)) - input
The handle of the window being destroyed.

DestroyWindowHook Parameter - ulReserved

ulReserved ([ULONG](#)) - input
Reserved.

DestroyWindowHook Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

DestroyWindowHook - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

hwnd ([HWND](#)) - input
The handle of the window being destroyed.

ulReserved ([ULONG](#)) - input
Reserved.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

DestroyWindowHook - Remarks

This hook is sent after the [WM_DESTROY](#) message has been sent and just before the window becomes invalid.

DialogProc

DialogProc - Syntax

This is a window procedure that automatically subclasses each instance of a dialog box.

```
#define INCL_WINDIALOGS /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HWND      hwnd;          /* Handle of the window to which the message applies. */
USHORT    usmsg;          /* Message identity. */
MPARAM    mpParam1;       /* Message parameter 1. */
MPARAM    mpParam2;       /* Message parameter 2. */
MRESULT    mresReply;     /* Message-return data. */
```

```
mresReply = DialogProc(hwnd, usmsg, mpParam1,  
                        mpParam2);
```

DialogProc Parameter - hwnd

hwnd (**HWND**) - input
Handle of the window to which the message applies.

DialogProc Parameter - usmsg

usmsg (**USHORT**) - input
Message identity.

DialogProc Parameter - mpParam1

mpParam1 (**MPARAM**) - input
Message parameter 1.

DialogProc Parameter - mpParam2

mpParam2 (**MPARAM**) - input
Message parameter 2.

DialogProc Return Value - mresReply

mresReply (**MRESULT**) - returns
Message-return data.

DialogProc - Parameters

hwnd ([HWND](#)) - input
Handle of the window to which the message applies.

usmsg ([USHORT](#)) - input
Message identity.

mpParam1 ([MPARAM](#)) - input
Message parameter 1.

mpParam2 ([MPARAM](#)) - input
Message parameter 2.

mresReply ([MRESULT](#)) - returns
Message-return data.

DialogProc - Remarks

This procedure is the same as any other window procedure, except that it can receive predefined window messages specific to dialog box windows.

Note: It does *not* receive the [WM_CREATE](#) message, but the same information is carried by the [WM_INITDLG](#) message, that is generated during the creation of a dialog-box window.

hwnd is always the window handle of the dialog-box window.

The dialog procedure typically processes only some of the messages passed to it. Any messages that it does not process must be passed to [WinDefFileDlgProc](#) if the dialog box is the standard file selection dialog, [WinDefFontDlgProc](#) if the dialog box is the standard font selection dialog box, or for all other dialog boxes, [WinDefDlgProc](#) (not [WinDefWindowProc](#)), because these perform the standard dialog-box processing for those messages.

FindWordHook

FindWordHook - Syntax

This hook allows an application to control where the [WinDrawText](#) function breaks a character string that is too long for the drawing rectangle.

```
#define INCL_WINHOOKS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

USHORT    usCodepage; /* Codepage to use. */
PSZ       pszText;    /* Text to break. */
ULONG     cb;         /* Maximum text size. */
ULONG     ich;        /* Break near here. */
PULONG    pichStart;  /* Where break began. */
PULONG    pichEnd;    /* Where break ended. */
PULONG    pichNext;   /* Where next word begins. */
BOOL      rc;         /* Success indicator. */

rc = FindWordHook(usCodepage, pszText, cb,
                 ich, pichStart, pichEnd, pichNext);
```

FindWordHook Parameter - usCodepage

usCodepage ([USHORT](#)) - input
Codepage to use.

This parameter contains the codepage identifier of the string to be formatted.

FindWordHook Parameter - pszText

pszText ([PSZ](#)) - input
Text to break.

This parameter contains a pointer to the actual string.

FindWordHook Parameter - cb

cb ([ULONG](#)) - input
Maximum text size.

This parameter contains a value specifying the number of bytes in the string.

FindWordHook Parameter - ich

ich ([ULONG](#)) - input
Break near here.

This parameter contains the index of the character in the string that intersects the right edge of the drawing rectangle.

FindWordHook Parameter - pichStart

pichStart ([PULONG](#)) - output
Where break began.

This parameter contains the index of the starting character of the intersecting word.

FindWordHook Parameter - pichEnd

pichEnd ([PULONG](#)) - output
Where break ended.

This parameter contains the index of the ending character of the intersecting word.

FindWordHook Parameter - pichNext

pichNext ([PULONG](#)) - output
Where next word begins.

This parameter contains the index of the starting character of the next word in the string.

FindWordHook Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE

If the find-word hook function returns TRUE, [WinDrawText](#) will only draw the string up to, but not including, the specified word.

FALSE

If the find-word hook function returns FALSE, [WinDrawText](#) formats the string in the default manner.

FindWordHook - Parameters

usCodepage ([USHORT](#)) - input
Codepage to use.

This parameter contains the codepage identifier of the string to be formatted.

pszText ([PSZ](#)) - input
Text to break.

This parameter contains a pointer to the actual string.

cb ([ULONG](#)) - input
Maximum text size.

This parameter contains a value specifying the number of bytes in the string.

ich ([ULONG](#)) - input
Break near here.

This parameter contains the index of the character in the string that intersects the right edge of the drawing rectangle.

pichStart ([PULONG](#)) - output
Where break began.

This parameter contains the index of the starting character of the intersecting word.

pichEnd ([PULONG](#)) - output
Where break ended.

This parameter contains the index of the ending character of the intersecting word.

pichNext ([PULONG](#)) - output
Where next word begins.

This parameter contains the index of the starting character of the next word in the string.

rc ([BOOL](#)) - returns
Success indicator.

TRUE

If the find-word hook function returns TRUE, [WinDrawText](#) will only draw the string up to, but not including, the specified word.

FALSE

If the find-word hook function returns FALSE, [WinDrawText](#) formats the string in the default manner.

FindWordHook - Remarks

The system calls this hook from within the [WinDrawText](#) function, if the DT_WORDBREAK flag is set. It lets the application have control of where the function [WinDrawText](#) should break for a string that is too long.

FlushBufHook

FlushBufHook - Syntax

This function is specific to OS/2 Version 2.1 or higher.

This hook allows applications to save data before the system reboots.

```
#define INCL_WINHOOKS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB hab; /* Application anchor block. */
BOOL rc; /* Return code. */

rc = FlushBufHook(hab);
```

FlushBufHook Parameter - hab

hab (HAB) - input
Application anchor block.

FlushBufHook Return Value - rc

rc (BOOL) - returns
Return code.

TRUE	Successful completion.
FALSE	An error occurred.

FlushBufHook - Parameters

hab ([HAB](#)) - input
Application anchor block.

rc ([BOOL](#)) - returns
Return code.

TRUE	Successful completion.
FALSE	An error occurred.

FlushBufHook - Remarks

This hook is called to notify applications that the system is rebooting due to a Ctrl+Alt+Del sequence being entered. It enables applications to write existing information to the hardfile immediately, avoiding loss of data before the system reboots.

Note: Do not use any of the Win or Gpi functions inside the hook routine. At the point in time that the hook routine is executing, these sub-systems may not be fully available because they might be partially shutdown.

HelpHook

HelpHook - Syntax

This hook processes help requests.

```
#define INCL_WINHOOKS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
ULONG     usMode;       /* Help mode. */
ULONG     idTopic;      /* Topic identifier. */
ULONG     idSubTopic;   /* Subtopic identifier. */
PRECTL    prcPosition; /* Rectangle. */
BOOL      rc;           /* Indicator as to whether next hook in the chain is called. */

rc = HelpHook(hab, usMode, idTopic, idSubTopic,
               prcPosition);
```

HelpHook Parameter - hab

hab (**HAB**) - input
Anchor-block handle.

HelpHook Parameter - usMode

usMode (**ULONG**) - input
Help mode.

This has one of the following values, indicating the mode from which help has been requested:

HLPM_FRAME	Standard (standard window)
HLPM_WINDOW	Standard (standard window)
HLPM_MENU	Menu mode

HelpHook Parameter - idTopic

idTopic (**ULONG**) - input
Topic identifier.

- In menu mode this is a pull-down window identity
- In message-box mode this is the message-box identity
- In standard mode this is a window identity.

HelpHook Parameter - idSubTopic

idSubTopic ([ULONG](#)) - input
Subtopic identifier.

- In menu mode this is a command identity
- In message-box mode this is a control identity
- In standard mode this is the identity of the window with the focus (-1 if none).

HelpHook Parameter - prcPosition

prcPosition ([PRECTL](#)) - input
Rectangle.

This indicates the screen area (in screen coordinates) from where the help was requested. It is provided to enable the help library to avoid covering that area.

- In menu mode it is the bounding rectangle of the selected item, or of the top level menu if value of the *idSubTopic* parameter is -1.
- In message-box mode it is the bounding rectangle of the button.
- In standard mode it is the bounding rectangle of the window with the focus, or of the window sent the message if the value of the *idSubTopic* parameter is -1.

Note: The data type [WRECT](#) can also be used, if supported by the language.

HelpHook Return Value - rc

rc ([BOOL](#)) - returns
Indicator as to whether next hook in the chain is called.

The message is always passed to the application.

TRUE	The next hook in the chain is not called.
FALSE	The next hook in the chain is called.

HelpHook - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

usMode ([ULONG](#)) - input
Help mode.

This has one of the following values, indicating the mode from which help has been requested:

HLPM_FRAME	Standard (standard window)
HLPM_WINDOW	Standard (standard window)
HLPM_MENU	Menu mode

idTopic ([ULONG](#)) - input
Topic identifier.

- In menu mode this is a pull-down window identity
- In message-box mode this is the message-box identity
- In standard mode this is a window identity.

idSubTopic ([ULONG](#)) - input
Subtopic identifier.

- In menu mode this is a command identity
- In message-box mode this is a control identity
- In standard mode this is the identity of the window with the focus (-1 if none).

prcPosition ([PRECTL](#)) - input
Rectangle.

This indicates the screen area (in screen coordinates) from where the help was requested. It is provided to enable the help library to avoid covering that area.

- In menu mode it is the bounding rectangle of the selected item, or of the top level menu if value of the *idSubTopic* parameter is -1.
- In message-box mode it is the bounding rectangle of the button.
- In standard mode it is the bounding rectangle of the window with the focus, or of the window sent the message if the value of the *idSubTopic* parameter is -1.

Note: The data type [WRECT](#) can also be used, if supported by the language.

rc ([BOOL](#)) - returns
Indicator as to whether next hook in the chain is called.

The message is always passed to the application.

TRUE	The next hook in the chain is not called.
FALSE	The next hook in the chain is called.

HelpHook - Remarks

Help-processing is done in two stages. The first stage is the creation of the [WM_HELP](#) message. This is done:

- From a [WM_CHAR](#) message by ACCELERATOR table translation, when the HELP accelerator option is specified.
- From an action-bar selection, when the MIS_HELP style is specified on the action-bar button.
- From a dialog-box push button, when the BS_HELP style is specified on the push button.
- From a message box, when the MB_HELP style is specified on the message box.

The [WM_HELP](#) message is sent to the active window, but will be seen by a modal loop if one is active.

The second stage of processing of help is the processing of the [WM_HELP](#) message.

The frame window procedure sees the [WM_HELP](#) message because the frame is usually the active window. It processes the [WM_HELP](#) message as follows:

- If the window with the focus is the FID_CLIENT frame control, it passes [WM_HELP](#) to the FID_CLIENT window.
- If the parent of the window with the focus is the FID_CLIENT frame control, it calls the help hook, specifying:

```
usMode = HLPM_WINDOW  
idTopic = frame-window id  
idSubTopic = focus-window id.
```

- If the parent of the focus window is not the FID_CLIENT frame control (for example, it may be the frame itself, or a second-level dialog control), it calls the hook, specifying:

```
usMode = HLPM_WINDOW  
idTopic = focus-window parent id  
idSubTopic = focus-window id.
```

The message box window procedure sees the [WM_HELP](#) message, because it subclasses the frame window. It processes the [WM_HELP](#) message by calling the help hook, specifying:

```
usMode = HLPM_MESSAGE  
idTopic = message id  
idSubTopic = control id.
```

The menu window procedure sees the [WM_HELP](#) message because it runs a modal loop. It processes the [WM_HELP](#) message by calling the help hook, specifying:

```
usMode = HLPM_MENU  
idTopic = menu id of pulldown  
idSubTopic = menu id of item.
```

The [WinDefWindowProc](#) function sees the [WM_HELP](#) message for a FID_CLIENT window if the client does not handle it itself. It calls the help hook, specifying:

```
usMode = HLPM_WINDOW  
idTopic = active-window id  
idSubTopic = focus-window id.
```

An application sees the [WM_HELP](#) message in its dialog procedure. The application can ignore the [WM_HELP](#) message, in which case the frame-window procedure action occurs (as described above) or it can simulate a call to the help hook itself, using:

```
usMode = HLPM_APPLICATION  
idTopic = any value  
idSubTopic = any value.
```

The input focus is never given to any of the standard frame controls, so help for these cannot be obtained.

InputHook

InputHook - Syntax

This hook filters messages from the input queue.

```
#define INCL_WINHOOKS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;      /* Anchor-block handle. */
PQMSG    pQmsg;    /* A PQMSG data structure. */
ULONG    fs;       /* Message removal options. */
BOOL     rc;       /* Processed indicator. */

rc = InputHook(hab, pQmsg, fs);
```

InputHook Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

InputHook Parameter - pQmsg

pQmsg ([PQMSG](#)) - input
A PQMSG data structure.

InputHook Parameter - fs

fs ([ULONG](#)) - input
Message removal options.

PM_REMOVE

PM_NOREMOVE Message is being removed from queue
Message is not being removed from queue.

InputHook Return Value - rc

rc (**BOOL**) - returns
Processed indicator.

TRUE The message is not passed on to the next hook in the chain or to the application
FALSE The message is passed on to the next hook in the chain or to the application.

InputHook - Parameters

hab (**HAB**) - input
Anchor-block handle.

pQmsg (**PQMSG**) - input
A PQMSG data structure.

fs (**ULONG**) - input
Message removal options.

PM_REMOVE Message is being removed from queue
PM_NOREMOVE Message is not being removed from queue.

rc (**BOOL**) - returns
Processed indicator.

TRUE The message is not passed on to the next hook in the chain or to the application
FALSE The message is passed on to the next hook in the chain or to the application.

InputHook - Remarks

This hook is called when messages are removed from an application queue, before being returned by [WinGetMsg](#) or [WinPeekMsg](#). It is called from within these functions just before resuming the application with the message that is returned. There are no restrictions on calls that may be made at this time.

InputHook - Topics

JournalPlaybackHook

JournalPlaybackHook - Syntax

This hook plays back recorded messages.

```
#define INCL_WINHOOKS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;      /* Anchor-block handle. */
BOOL     fSkip;    /* Indicator as to whether the next message should be played back. */
PQMSG    pQmsg;    /* Data structure where the message to be played back is returned. */
ULONG    ulTime;   /* Waiting time. */

ulTime = JournalPlaybackHook(hab, fSkip, pQmsg);
```

JournalPlaybackHook Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

JournalPlaybackHook Parameter - fSkip

fSkip ([BOOL](#)) - input
Indicator as to whether the next message should be played back.

TRUE

The journal playback hook skips to the next message. The *pQmsg* parameter is NULL in this case. The next hook in the chain is not called.

FALSE

The journal playback hook returns the next available message. The same message is returned each time, until it is skipped with a call where this parameter is TRUE.

JournalPlaybackHook Parameter - pQmsg

pQmsg ([PQMSG](#)) - input

Data structure where the message to be played back is returned.

When this hook is called, the field of the [QMSG](#) structure is initialized to the current time. This can be used to determine whether the next message is ready or not. This value must be used for any delta calculations performed by the hook procedure, rather than the result of [WinGetCurrentTime](#).

JournalPlaybackHook Return Value - ulTime

ulTime ([ULONG](#)) - returns

Waiting time.

The time to wait (in milliseconds) before processing the current message.

JournalPlaybackHook - Parameters

hab ([HAB](#)) - input

Anchor-block handle.

fSkip ([BOOL](#)) - input

Indicator as to whether the next message should be played back.

TRUE

The journal playback hook skips to the next message. The *pQmsg* parameter is NULL in this case. The next hook in the chain is not called.

FALSE

The journal playback hook returns the next available message. The same message is returned each time, until it is skipped with a call where this parameter is TRUE.

pQmsg ([PQMSG](#)) - input

Data structure where the message to be played back is returned.

When this hook is called, the field of the [QMSG](#) structure is initialized to the current time. This can be used to determine whether the next message is ready or not. This value must be used for any delta calculations performed by the hook procedure, rather than the result of [WinGetCurrentTime](#).

ulTime ([ULONG](#)) - returns

Waiting time.

The time to wait (in milliseconds) before processing the current message.

JournalPlaybackHook - Remarks

This hook is called whenever a message is required to be played back.

JournalPlaybackHook - Topics

JournalRecordHook

JournalRecordHook - Syntax

This hook records user-input messages.

```
#define INCL_WINHOOKS /* Or use INCL_WIN, INCL_PM, */  
#include <os2.h>  
  
HAB      hab;      /* Anchor-block handle. */  
PQMSG    pQmsg;    /* Data structure that contains the message to be recorded. */  
  
JournalRecordHook(hab, pQmsg);
```

JournalRecordHook Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

JournalRecordHook Parameter - pQmsg

pQmsg ([PQMSG](#)) - input
Data structure that contains the message to be recorded.

The field of the [QMSG](#) structure is also set when the hook is called.

JournalRecordHook - Return Value

There is no return value for this hook.

JournalRecordHook - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

pQmsg ([PQMSG](#)) - input
Data structure that contains the message to be recorded.
The field of the [QMSG](#) structure is also set when the hook is called.

There is no return value for this hook.

JournalRecordHook - Remarks

This hook is called *after* raw input is translated to [WM_CHAR](#) or [WM_BUTTON1DBLCLK](#) messages.

The next hook in the chain is always called, and the message is always passed to the application.

[JournalPlaybackHook](#) hook does not receive any input played back by this hook. This prevents feedback situations where input is played back a number of times.

LoaderHook

LoaderHook - Syntax

This hook allows the library and procedure loading and deleting calls to be intercepted.

```
#define INCL_WINHOOKS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
LONG     idContext;    /* Origin of call to hook. */
PSZ      pszLibname;   /* Library name. */
PHLIB    hlib;         /* Pointer to a library handle. */
PSZ      pszProcname;  /* Procedure name. */
PFNWP    wndProc;      /* Window procedure identifier. */
PBOOL    pfSuccess;    /* Success indicator. */
BOOL     rc;           /* Processing indicator. */

rc = LoaderHook(hab, idContext, pszLibname,
                hlib, pszProcname, wndProc, pfSuccess);
```

LoaderHook Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

LoaderHook Parameter - idContext

idContext ([LONG](#)) - input
Origin of call to hook.

```
LHK_DELETEPROC    WinDeleteProcedure
LHK_DELETELIB     WinDeleteLibrary
LHK_LOADPROC      WinLoadProcedure
LHK_LOADLIB       WinLoadLibrary
```

LoaderHook Parameter - pszLibname

pszLibname ([PSZ](#)) - input
Library name.

This is the same as the library name in the *pszLibname* parameter of the [WinLoadLibrary](#) function.

LoaderHook Parameter - hlib

hlib ([PHLIB](#)) - in/out
Pointer to a library handle.

This is the same as the library handle in the *hlibLibhandle* parameter of the [WinLoadProcedure](#) function or the *hlibLibhandle* parameter of the [WinDeleteLibrary](#) function.

If the *idContext* parameter is set to LHK_LOADLIB, then this hook must set the value of this parameter to the handle of the loaded library or to NULLHANDLE if the load fails.

LoaderHook Parameter - pszProcname

pszProcname ([PSZ](#)) - input
Procedure name.

This is the same as the procedure name in the *pszProcname* parameter of the [WinLoadProcedure](#) function.

LoaderHook Parameter - wndProc

wndProc ([PFNWP](#)) - input
Window procedure identifier.

This is the same as the library name in the *pwndproc* parameter of the [WinDeleteProcedure](#) function.

If the *idContext* parameter is set to LHK_LOADPROC, then this hook must set the value of this parameter to the handle of the loaded procedure or to NULL if the load fails.

LoaderHook Parameter - pfSuccess

pfSuccess ([PBOOL](#)) - in/out
Success indicator.

TRUE	Library or procedure loaded or deleted successfully.
FALSE	Library or procedure not loaded or deleted successfully.

LoaderHook Return Value - rc

rc ([BOOL](#)) - returns
Processing indicator.

TRUE	Do not call next hook in chain.
FALSE	Call next hook in chain.

LoaderHook - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

idContext ([LONG](#)) - input
Origin of call to hook.

LHK_DELETEPROC	WinDeleteProcedure
LHK_DELETELIB	WinDeleteLibrary
LHK_LOADPROC	WinLoadProcedure
LHK_LOADLIB	WinLoadLibrary

pszLibname ([PSZ](#)) - input
Library name.

This is the same as the library name in the *pszLibname* parameter of the [WinLoadLibrary](#) function.

hlib ([PHLIB](#)) - in/out
Pointer to a library handle.

This is the same as the library handle in the *hlibLibhandle* parameter of the [WinLoadProcedure](#) function or the *hlibLibhandle* parameter of the [WinDeleteLibrary](#) function.

If the *idContext* parameter is set to LHK_LOADLIB, then this hook must set the value of this parameter to the handle of the loaded library or to NULLHANDLE if the load fails.

pszProcname ([PSZ](#)) - input
Procedure name.

This is the same as the procedure name in the *pszProcname* parameter of the [WinLoadProcedure](#) function.

wndProc ([PFNWP](#)) - input
Window procedure identifier.

This is the same as the library name in the *pwndproc* parameter of the [WinDeleteProcedure](#) function.

If the *idContext* parameter is set to LHK_LOADPROC, then this hook must set the value of this parameter to the handle of the loaded

procedure or to NULL if the load fails.

pfSuccess ([PBOOL](#)) - in/out
Success indicator.

TRUE	Library or procedure loaded or deleted successfully.
FALSE	Library or procedure not loaded or deleted successfully.

rc ([BOOL](#)) - returns
Processing indicator.

TRUE	Do not call next hook in chain.
FALSE	Call next hook in chain.

LoaderHook - Remarks

If the hook attempts a load or deletion which is unsuccessful, then the hook must establish the relevant error information.

LockupHook

LockupHook - Syntax

This function is specific to OS/2 Version 2.1 or higher.

This hook is called when the system locks itself up.

```
#define INCL_WINHOOKS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;          /* The application anchor block. */
HWND     hwndLockupFrame; /* The frame window of the lockup panel. */

LockupHook(hab, hwndLockupFrame);
```

LockupHook Parameter - hab

hab ([HAB](#)) - input
The application anchor block.

LockupHook Parameter - hwndLockupFrame

hwndLockupFrame ([HWND](#)) - input
The frame window of the lockup panel.

LockupHook - Return Value

There is no return value for this hook.

LockupHook - Parameters

hab ([HAB](#)) - input
The application anchor block.

hwndLockupFrame ([HWND](#)) - input
The frame window of the lockup panel.

There is no return value for this hook.

LockupHook - Remarks

The *hwndLockupFrame* parameter contains the frame window handle of the lockup dialog. All HK_LOCKUP hooks registered with the system are called when the system locks itself up. All HK_LOCKUP hooks must be system hooks, not message queue hooks.

Application programs that create other lockup password input windows by hooking the HK_LOCKUP system hook can use [WinUnlockSystem](#) to force the system to unlock when another form of input is detected other than mouse or keyboard. For example, a pen gesture or some voice input or signature recognition.

MsgControlHook

MsgControlHook - Syntax

This hook allows the call to determine the flow of messages to be intercepted.

```
#define INCL_WINHOOKS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;           /* Anchor-block handle. */
LONG     idContext;     /* Origin of call to hook. */
HWND     hwnd;         /* Window handle. */
PSZ      pszClassName; /* Window class name. */
ULONG    usMsgClass;    /* Message class. */
LONG     idControl;     /* Control setting. */
PBOOL    fSuccess;      /* Success indicator. */
BOOL     rc;           /* Processing indicator. */

rc = MsgControlHook(hab, idContext, hwnd,
    pszClassName, usMsgClass, idControl,
    fSuccess);
```

MsgControlHook Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

MsgControlHook Parameter - idContext

idContext ([LONG](#)) - input
Origin of call to hook.

MCHK_CLASSMSGINTEREST
[WinSetClassMsgInterest](#)
MCHK_MSGINTEREST
[WinSetMsgInterest](#)
MCHK_MSGMODE
[WinSetMsgMode](#)
MCHK_SYNCHRONISATION
[WinSetSynchroMode](#)

MsgControlHook Parameter - hwnd

hwnd ([HWND](#)) - input
Window handle.

This is the same as the window handle in the *hwnd* parameter of the [WinSetMsgInterest](#) function.

MsgControlHook Parameter - pszClassName

pszClassName ([PSZ](#)) - input
Window class name.

This is the same as the window class name in the *pszClassName* parameter of the [WinSetClassMsgInterest](#) function.

MsgControlHook Parameter - usMsgClass

usMsgClass ([ULONG](#)) - input
Message class.

This is the same as the message class in the *ulMsgClass* parameter of the [WinSetMsgInterest](#) and the [WinSetClassMsgInterest](#) functions.

MsgControlHook Parameter - idControl

idControl (**LONG**) - input
Control setting.

The setting varies with the value of the *idContext* parameter.

For MCHK_CLASSMSGINTEREST, it can be SMI_INTEREST, or SMI_NOINTEREST, or SMI_AUTODISPATCH.

For MCHK_MSGINTEREST, it can be SMI_INTEREST, or SMI_NOINTEREST, or SMI_RESET, or SMI_AUTODISPATCH.

For MCHK_MSGMODE, it can be SMD_DELAYED or SMD_IMMEDIATE.

For MCHK_SYNCHRONISATION, it can be SSM_SYNCHRONOUS, or SSM_ASYNCHRONOUS, or SSM_MIXED.

MsgControlHook Parameter - fSuccess

fSuccess (**PBOOL**) - in/out
Success indicator.

TRUE	Mode or interest successfully set.
FALSE	Mode or interest not successfully set.

MsgControlHook Return Value - rc

rc (**BOOL**) - returns
Processing indicator.

TRUE	Do not call next hook in chain
FALSE	Call next hook in chain.

MsgControlHook - Parameters

hab (**HAB**) - input
Anchor-block handle.

idContext (**LONG**) - input
Origin of call to hook.

MCHK_CLASSMSGINTEREST	WinSetClassMsgInterest
MCHK_MSGINTEREST	WinSetMsgInterest
MCHK_MSGMODE	WinSetMsgMode
MCHK_SYNCHRONISATION	

WinSetSynchroMode

hwnd ([HWND](#)) - input
Window handle.

This is the same as the window handle in the *hwnd* parameter of the [WinSetMsgInterest](#) function.

pszClassName ([PSZ](#)) - input
Window class name.

This is the same as the window class name in the *pszClassName* parameter of the [WinSetClassMsgInterest](#) function.

usMsgClass ([ULONG](#)) - input
Message class.

This is the same as the message class in the *uiMsgClass* parameter of the [WinSetMsgInterest](#) and the [WinSetClassMsgInterest](#) functions.

idControl ([LONG](#)) - input
Control setting.

The setting varies with the value of the *idContext* parameter.

For MCHK_CLASSMSGINTEREST, it can be SMI_INTEREST, or SMI_NOINTEREST, or SMI_AUTODISPATCH.

For MCHK_MSGINTEREST, it can be SMI_INTEREST, or SMI_NOINTEREST, or SMI_RESET, or SMI_AUTODISPATCH.

For MCHK_MSGMODE, it can be SMD_DELAYED or SMD_IMMEDIATE.

For MCHK_SYNCHRONISATION, it can be SSM_SYNCHRONOUS, or SSM_ASYNCHRONOUS, or SSM_MIXED.

fSuccess ([PBOOL](#)) - in/out
Success indicator.

TRUE	Mode or interest successfully set.
FALSE	Mode or interest not successfully set.

rc ([BOOL](#)) - returns
Processing indicator.

TRUE	Do not call next hook in chain
FALSE	Call next hook in chain.

MsgControlHook - Remarks

If the hook is unable to alter the message control state, then the hook must establish the relevant error information.

[Glossary](#)

MsgFilterHook

MsgFilterHook - Syntax

This hook filters messages from inside a mode loop.

```
#define INCL_WINHOOKS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;      /* Anchor-block handle. */
PQMSG    pQmsg;    /* A queue message data structure. */
ULONG    msgf;     /* Context in which the hook has been called. */
BOOL     rc;       /* Processed indicator. */

rc = MsgFilterHook(hab, pQmsg, msgf);
```

MsgFilterHook Parameter - hab

hab (**HAB**) - input
Anchor-block handle.

MsgFilterHook Parameter - pQmsg

pQmsg (**PQMSG**) - input
A queue message data structure.

MsgFilterHook Parameter - msgf

msgf (**ULONG**) - input
Context in which the hook has been called.

MSGF_DIALOGBOX
Dialog-box mode loop.

MSGF_TRACK
Window-movement and size tracking. When this hook is used the **TRACKINFO** structure specified the *ptiTrackinfo* parameter of the **WinTrackRect** function is updated to give the current state before the hook is called. Only the

parameters are updated.

MSGF_DRAG

Direct manipulation mode loop.

MSGF_DDEPOSTMSG

DDE post message mode loop.

MsgFilterHook Return Value - rc

rc (**BOOL**) - returns

Processed indicator.

TRUE

The message is not passed on to the next hook in the chain or to the application

FALSE

The message is passed on to the next hook in the chain or to the application.

MsgFilterHook - Parameters

hab (**HAB**) - input

Anchor-block handle.

pQmsg (**PQMSG**) - input

A queue message data structure.

msgf (**ULONG**) - input

Context in which the hook has been called.

MSGF_DIALOGBOX

Dialog-box mode loop.

MSGF_TRACK

Window-movement and size tracking. When this hook is used the **TRACKINFO** structure specified the *ptTrackinfo* parameter of the **WinTrackRect** function is updated to give the current state before the hook is called. Only the parameters are updated.

MSGF_DRAG

Direct manipulation mode loop.

MSGF_DDEPOSTMSG

DDE post message mode loop.

rc (**BOOL**) - returns

Processed indicator.

TRUE

The message is not passed on to the next hook in the chain or to the application

FALSE

The message is passed on to the next hook in the chain or to the application.

MsgFilterHook - Remarks

This hook is called inside any of the system-mode loops, for instance, during size-tracking or move-tracking, or while a dialog box or menu is displayed.

The [WM_QUIT](#) message is passed to this hook, if it occurs during a mode loop.

MsgInputHook

MsgInputHook - Syntax

This function is specific to OS/2 Version 2.1 or higher.

```
#define INCL_WINHOOKS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
PQMSG    pQmsg;        /* Queue message data structure. */
BOOL      fSkip;       /* Skip message flag. */
PBOOL    pfNoRecord;   /* Record message flag. */
BOOL      rc;          /* Return code. */

rc = MsgInputHook(hab, pQmsg, fSkip, pfNoRecord);
```

MsgInputHook Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

MsgInputHook Parameter - pQmsg

pQmsg ([PQMSG](#)) - in/out
Queue message data structure.

A queue message data structure to be filled in with a simulated mouse or keyboard message.

MsgInputHook Parameter - fSkip

fSkip ([BOOL](#)) - input
Skip message flag.

TRUE

The hook should advance to the next message.

No message is passed in when *fSkip* is set to TRUE. The *pQmsg* parameter is NULL in this case.

When the hook is called with *fSkip* set to TRUE and there are no further messages to pass in, the MsgInputHook hook must be released using [WinReleaseHook](#).

FALSE

The current message should be returned.

As long as the hook procedure is called with *fSkip* set to FALSE, the hook must continue to return the *same* message.

MsgInputHook Parameter - pfNoRecord

pfNoRecord ([PBOOL](#)) - output
Record message flag.

TRUE

The message will not be recorded in the [JournalRecordHook](#) hook.

Unless journal recording is specifically needed by the application, this parameter should always be TRUE.

FALSE

The message will be recorded in the [JournalRecordHook](#) hook.

MsgInputHook Return Value - rc

rc ([BOOL](#)) - returns
Return code.

TRUE

The [QMSG](#) structure contains the current message to be passed in for handling.

FALSE

The [QMSG](#) structure was not filled in. There are no further messages to pass in.

MsgInputHook - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

pQmsg ([PQMSG](#)) - in/out
Queue message data structure.

A queue message data structure to be filled in with a simulated mouse or keyboard message.

fSkip ([BOOL](#)) - input
Skip message flag.

TRUE

The hook should advance to the next message.

No message is passed in when *fSkip* is set to TRUE. The *pQmsg* parameter is NULL in this case.

When the hook is called with *fSkip* set to TRUE and there are no further messages to pass in, the MsgInputHook hook must be released using [WinReleaseHook](#).

FALSE

The current message should be returned.

As long as the hook procedure is called with *fSkip* set to FALSE, the hook must continue to return the *same* message.

pfNoRecord ([PBOOL](#)) - output
Record message flag.

TRUE

The message will not be recorded in the [JournalRecordHook](#) hook.

Unless journal recording is specifically needed by the application, this parameter should always be TRUE.

FALSE

The message will be recorded in the [JournalRecordHook](#) hook.

rc ([BOOL](#)) - returns
Return code.

TRUE

The [QMSG](#) structure contains the current message to be passed in for handling.

FALSE

The [QMSG](#) structure was not filled in. There are no further messages to pass in.

MsgInputHook - Remarks

This hook is intended for simulated user input, and only mouse and keyboard messages should be passed in. All other messages will be discarded. Mouse and keyboard messages injected into this hook will have the same effect as if they were generated by the mouse or keyboard device driver. The messages are routed in the same manner as normal user input.

The *pfNoRecord* parameter defaults to TRUE, implying that messages received from the MsgInputHook hook will not be recorded in the [JournalRecordHook](#) hook. Injected messages should not be recorded unless necessary.

When all messages have been passed in the application must remove the MsgInputHook hook using [WinReleaseHook](#).

ProgramListEntryHook

ProgramListEntryHook - Syntax

This hook chain is called every time a program-list call or initialization file call is invoked by an application. It is called before the call is run.

```
#define INCL_FnDrEnPt
#include <os2.h>

HAB      hab;
PRFHOOKPARMS pProfileHookParams;
BOOL     fNoExecute;
BOOL     rc;

rc = ProgramListEntryHook(hab, pProfileHookParams,
    fNoExecute);
```

ProgramListEntryHook Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

ProgramListEntryHook Parameter - pProfileHookParams

pProfileHookParams ([PRFHOOKPARMS](#)) - input

Profile hook parameters. These identify the call and give its parameters and return code. See [PRFHOOKPARMS](#) for more information.

ProgramListEntryHook Parameter - fNoExecute

fNoExecute ([BOOL](#)) - output

Suppress indicator.

TRUE

If this is set by any hook procedure, no further processing of the call is done.

FALSE

If all hook procedures set *fNoExecute* to FALSE, the call is processed normally.

ProgramListEntryHook Return Value - rc

rc ([BOOL](#)) - returns

Processed indicator.

TRUE

The next hook in the chain is not called.

FALSE

The next hook in the chain is called.

ProgramListEntryHook - Parameters

hab ([HAB](#)) - input

Anchor-block handle.

pProfileHookParams ([PRFHOOKPARMS](#)) - input

Profile hook parameters. These identify the call and give its parameters and return code. See [PRFHOOKPARMS](#) for more information.

fNoExecute ([BOOL](#)) - output

Suppress indicator.

TRUE

If this is set by any hook procedure, no further processing of the call is done.

FALSE

If all hook procedures set *fNoExecute* to FALSE, the call is processed normally.

rc ([BOOL](#)) - returns

Processed indicator.

TRUE

FALSE	The next hook in the chain is not called.
	The next hook in the chain is called.

ProgramListEntryHook - Remarks

This hook, together with [ProgramListExitHook](#) lets applications or system components to do the following:

1. Implement the initialization file and program list partially, while retaining the existing implementation. For example, read-only requests could be satisfied from memory, rather than from disk.
2. Redirect initialization-file operations on a particular group to an alternative (opened) profile. For example, in a multiple-user environment, a LAN program might choose to redirect profile groups that are hardware-dependent, rather than user-dependent, to the system-initialization file.

ProgramListEntryHook - Topics

ProgramListExitHook

ProgramListExitHook - Syntax

This hook chain is called every time a program-list call or initialization file call is invoked by an application. It is called before the call is run.

```
#define INCL_FnDrEnPt
#include <os2.h>

HAB          hab;
PRFHOOKPARMS pProfileHookParams;
BOOL         rc;

rc = ProgramListExitHook(hab, pProfileHookParams);
```

ProgramListExitHook Parameter - hab

hab ([HAB](#)) - input
Anchor block handle.

ProgramListExitHook Parameter - pProfileHookParams

pProfileHookParams ([PRFHOOKPARMS](#)) - input
Profile hook parameters. These identify the call and give its parameters and return code. See [PRFHOOKPARMS](#).

ProgramListExitHook Return Value - rc

rc ([BOOL](#)) - returns
Process indicator.

TRUE	The next hook in the chain is not called.
FALSE	The next hook in the chain is called.

ProgramListExitHook - Parameters

hab ([HAB](#)) - input
Anchor block handle.

pProfileHookParams ([PRFHOOKPARMS](#)) - input
Profile hook parameters. These identify the call and give its parameters and return code. See [PRFHOOKPARMS](#).

rc ([BOOL](#)) - returns
Process indicator.

TRUE	The next hook in the chain is not called.
FALSE	The next hook in the chain is called.

ProgramListExitHook - Remarks

This hook, together with its counterpart, [ProgramListEntryHook](#), lets applications or system components:

1. Implement the initialization file and program list partially, whilst retaining the existing implementation. For example, read-only requests could be satisfied from memory, rather than from disk.
2. Redirect initialization-file operations on a particular group to an alternative (opened) profile. For example, in a multiple-user

environment, a LAN program might choose to redirect profile groups that are hardware-dependent, rather than user-dependent, to the system-initialization file.

RegisterUserHook

RegisterUserHook - Syntax

This hook is called whenever a user message or data type is registered.

```
#define INCL_WINHOOKS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;          /* The application anchor block. */
ULONG    cUshort;      /* Number of data type codes. */
PUSHORT  arRMP;        /* Array of data type codes. */
PBOOL    fRegistered;  /* Flag indicating that a message or data type was registered. */
BOOL     rc;           /* Success indicator. */

rc = RegisterUserHook(hab, cUshort, arRMP,
    fRegistered);
```

RegisterUserHook Parameter - hab

hab ([HAB](#)) - input
The application anchor block.

RegisterUserHook Parameter - cUshort

cUshort ([ULONG](#)) - input
Number of data type codes.

For data types, this parameter is the number of data type codes in *arRMP*, This value must not be less than one.

For messages, this parameter is set to 0.

RegisterUserHook Parameter - arRMP

arRMP ([PUSHORT](#)) - input
Array of data type codes.

For data types, this parameter is an array of data type codes. For messages, this parameter is set to NULL.

Valid data types are the system-defined data types and their pointer equivalents, application-defined data types and their pointer equivalents, and control data types. Note that not all of the data types that occur in the CPI can be specified in this function.

A control data type is followed by one or more entries in the *arRMP* array that are interpreted in a special way. Control data types allow arrays, offsets, and lengths to be defined.

DTYP_WRECT
DTYP_XYWINSIZE

See [WNDPARAMS](#).
See [WPOINT](#).
See [WRECT](#).
See [XYWINSIZE](#).

Pointer Data Type

DTYP_P*

Pointer to an item of data type DTYP_*, where DTYP_* is one of the data types in the preceding lists. The value of a pointer data type is the value of the corresponding non-pointer data type prefixed with a minus to make it negative.

Minimum Application Data Type

DTYP_USER

Minimum value for application-defined non-pointer data types.

Control Data Type

DTYP_CTL_ARRAY

This starts a sequence of three array elements that define an array; the array resides in the structure being defined, and may have a fixed number of elements or a variable number of elements.

The following describes the possible elements:
n DTYP_CTL_ARRAY

n+1 Data type of array data.

n+2 Minus the number of elements in the array (for an array of fixed size). This component must have a suitable numeric data type. The index is zero-based.

DTYP_CTL_LENGTH

This starts a sequence of four array elements that define a structure component containing the length of part or all of the structure. The length component resides at this point in the structure.

The following describes the possible elements:
n DYP_CTL_LENGTH

n+1 Data type of structure component that contains the length (must be a suitable numeric data type).

n+2 The index of the element. A value of -1 denotes the start of the structure. This index is zero-based.

The element specified must not be one that is the second or subsequent element in a DTYP_CTL_* sequence of elements.

N+3 The index of the element. It must not be less than the value contained in element n+2. A value of -1 denotes the end of the structure. The index is zero-based.

The element specified must not be one that is the second or subsequent element in a DTYP_CTL_* sequence of elements.

If the value is -1, the length includes all offset data residing at the end of the structure.

DTYP_CTL_OFFSET

This starts a sequence of four array elements that define data addressed by an offset. The offset resides at this point in the structure, and contains the offset in bytes of the data from the start of the *outermost* structure in which this component resides. The data addressed by the offset must occupy storage following the fixed part of the structure. The data may be scalar data or array data.

DTYP_CTL_PARRAY	The following describes the possible elements:	
	n	DTYP_CTL_OFFSET
	n+1	Data type of the structure component that contains the offset (must be a suitable unsigned numeric data type).
	n+2	Data type of offset data.
	n+3	Minus the number of elements in the array (for an array of fixed size). This component must have a suitable numeric data type; the array-size element may occur earlier or later in the structure. This index is zero-based.
		A value of -1 indicates that the data is not an array.
		This starts a sequence of three array elements that define a pointer to an array. The pointer resides at this point in the structure, and the array resides elsewhere. The array can have a fixed or variable number of elements.
		The following describes the possible elements:
		n DTYP_CTL_PARRAY
		n+1 Data type of array data.
		n+2 Minus the number of elements in the array (for an array of fixed size). This component must have a suitable numeric data type. The array-size element may occur earlier or later in the structure. The index is zero-based.

RegisterUserHook Parameter - fRegistered

fRegistered (PBOOL) - input
Flag indicating that a message or data type was registered.

TRUE	Message/data type was registered.
FALSE	Message/data type was not registered.

RegisterUserHook Return Value - rc

rc (BOOL) - returns
Success indicator.

TRUE	Successful completion
FALSE	Errors occurred.

RegisterUserHook - Parameters

hab ([HAB](#)) - input
The application anchor block.

cUshort ([ULONG](#)) - input
Number of data type codes.

For data types, this parameter is the number of data type codes in *arRMP*. This value must not be less than one.

For messages, this parameter is set to 0.

arRMP ([PUSHORT](#)) - input
Array of data type codes.

For data types, this parameter is an array of data type codes. For messages, this parameter is set to NULL.

Valid data types are the system-defined data types and their pointer equivalents, application-defined data types and their pointer equivalents, and control data types. Note that not all of the data types that occur in the CPI can be specified in this function.

A control data type is followed by one or more entries in the *arRMP* array that are interpreted in a special way. Control data types allow arrays, offsets, and lengths to be defined.

Pointer Data Type

DTYP_P*

Pointer to an item of data type DTYP_*, where DTYP_* is one of the data types in the preceding lists. The value of a pointer data type is the value of the corresponding non-pointer data type prefixed with a minus to make it negative.

Minimum Application Data Type

DTYP_USER

Minimum value for application-defined non-pointer data types.

Control Data Type

DTYP_CTL_ARRAY

This starts a sequence of three array elements that define an array; the array resides in the structure being defined, and may have a fixed number of elements or a variable number of elements.

The following describes the possible elements:

- | | |
|-----|---|
| n | DTYP_CTL_ARRAY |
| n+1 | Data type of array data. |
| n+2 | Minus the number of elements in the array (for an array of fixed size). This component must have a suitable numeric data type. The index is zero-based. |

DTYP_CTL_LENGTH

This starts a sequence of four array elements that define a structure component containing the length of part or all of the structure. The length component resides at this point in the structure.

The following describes the possible elements:

- | | |
|-----|--|
| n | DYP_CTL_LENGTH |
| n+1 | Data type of structure component that contains the length (must be a suitable numeric data type). |
| n+2 | The index of the element. A value of -1 denotes the start of the structure. This index is zero-based.

The element specified must not be one that is the second or subsequent element in a DTYP_CTL_* sequence of elements. |
| N+3 | The index of the element. It must not be less than the value contained in element n+2. A value of -1 denotes the end of the structure. The index is zero-based.

The element specified must not be one that is the second or subsequent element in a DTYP_CTL_* sequence of elements.

If the value is -1, the length includes all offset data residing at the end of the structure. |

DTYP_CTL_OFFSET

This starts a sequence of four array elements that define data addressed by an offset. The offset resides at this point in the structure, and contains the offset in bytes of the data from the start of the *outermost* structure in which this component resides. The data addressed by the offset must occupy storage following the fixed part of the structure. The data may be scalar

		data or array data.
		The following describes the possible elements:
DTYP_CTL_OFFSET	n	
	n+1	Data type of the structure component that contains the offset (must be a suitable unsigned numeric data type).
	n+2	Data type of offset data.
	n+3	Minus the number of elements in the array (for an array of fixed size). This component must have a suitable numeric data type; the array-size element may occur earlier or later in the structure. This index is zero-based.
		A value of -1 indicates that the data is not an array.
DTYP_CTL_PARRAY		This starts a sequence of three array elements that define a pointer to an array. The pointer resides at this point in the structure, and the array resides elsewhere. The array can have a fixed or variable number of elements.
		The following describes the possible elements:
DTYP_CTL_PARRAY	n	
	n+1	Data type of array data.
	n+2	Minus the number of elements in the array (for an array of fixed size). This component must have a suitable numeric data type. The array-size element may occur earlier or later in the structure. The index is zero-based.
fRegistered (PBOOL) - input		Flag indicating that a message or data type was registered.
TRUE		
	Message/data type was registered.	
FALSE		
	Message/data type was not registered.	
rc (BOOL) - returns		Success indicator.
TRUE		
	Successful completion	
FALSE		
	Errors occurred.	

RegisterUserHook - Remarks

This hook is called when a call is made to either [WinRegisterUserDatatype](#) or [WinRegisterUserMsg](#).

RegisterUserHook - Topics

Select an item:
[Syntax](#)

[Parameters](#)
[Returns](#)
[Remarks](#)
[Glossary](#)

SendMsgHook

SendMsgHook - Syntax

This hook filters messages sent by the [WinSendMsg](#) function.

```
#define INCL_WINHOOKS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
PSMHSTRUCT psmh;       /* Pointer to a send message hook structure. */
BOOL      fInterTask;  /* Intertask indicator. */

SendMsgHook(hab, psmh, fInterTask);
```

SendMsgHook Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

SendMsgHook Parameter - psmh

psmh ([PSMHSTRUCT](#)) - input
Pointer to a send message hook structure.

This a structure contains the parameters to the [WinSendMsg](#) function.

SendMsgHook Parameter - fInterTask

fInterTask ([BOOL](#)) - input
Intertask indicator.

TRUE	
FALSE	The message is sent between tasks (intertask).
	The message is sent within a task (intratask).

SendMessageHook - Return Value

There is no return value for this hook.

SendMessageHook - Parameters

hAb ([HAB](#)) - input
Anchor-block handle.

psmh ([PSMHSTRUCT](#)) - input
Pointer to a send message hook structure.

This structure contains the parameters to the [WinSendMessage](#) function.

fIntertask ([BOOL](#)) - input
Intertask indicator.

TRUE	
FALSE	The message is sent between tasks (intertask).
	The message is sent within a task (intratask).

There is no return value for this hook.

SendMessageHook - Remarks

This hook may be called whenever a window procedure is called via the [WinSendMessage](#) function.

It is called in the context of the sender, whereby if the sender has a queue hook installed it is called, but if the receiver has a queue hook installed it is not called.

The next hook in the chain is always called.

SendMessageHook - Topics

Select an item:

[Syntax](#)
[Parameters](#)
[Returns](#)

ThunkProc

ThunkProc - Syntax

This procedure provides pointer conversion for application-defined messages.

```
#define INCL_NONE
#include <os2.h>

HWND      hwnd;      /* Window handle. */
USHORT    usmsg;      /* Message identity. */
MPARAM    mpParam1;   /* Message parameter 1. */
MPARAM    mpParam2;   /* Message parameter 2. */
PFNWP     pWndProc;   /* Window-procedure identifier. */
MRESULT    mresReply; /* Message-return data. */

mresReply = ThunkProc(hwnd, usmsg, mpParam1,
                      mpParam2, pWndProc);
```

ThunkProc Parameter - hwnd

hwnd (**HWND**) - input
Window handle.

ThunkProc Parameter - usmsg

usmsg (**USHORT**) - input
Message identity.

This is an application-defined message. The value is greater than or equal to WM_USER.

ThunkProc Parameter - mpParam1

mpParam1 (**MPARAM**) - input
Message parameter 1.

ThunkProc Parameter - mpParam2

mpParam2 (**MPARAM**) - input
Message parameter 2.

ThunkProc Parameter - pWndProc

pWndProc (**PFNWP**) - input
Window-procedure identifier.

ThunkProc Return Value - mresReply

mresReply (**MRESULT**) - returns
Message-return data.

ThunkProc - Parameters

hwnd (**HWND**) - input
Window handle.

usmsg (**USHORT**) - input
Message identity.

This is an application-defined message. The value is greater than or equal to WM_USER.

mpParam1 (**MPARAM**) - input
Message parameter 1.

mpParam2 (**MPARAM**) - input
Message parameter 2.

pWndProc (**PFNWP**) - input
Window-procedure identifier.

mresReply (**MRESULT**) - returns
Message-return data.

ThunkProc - Remarks

Pointer conversion is normally performed automatically by the operating system. An application needs to provide its own pointer-conversion procedures only for application-defined messages which may be passed from 16-bit code to 32-bit code.

A pointer-conversion procedure is associated with a window by the [WinSetWindowThunkProc](#) and [WinSetClassThunkProc](#) functions.

The logic of the pointer-conversion procedure is as follows:

1. Convert each message parameter, if necessary. This may include converting any data structures to which the parameter points.
2. Call the window procedure referenced by the *pWndProc* parameter, supplying as arguments *hwnd*, *usmsg*, *mpParam1* and *mpParam2*.
3. Collect the return value and, if necessary, convert it.

Note that structures to which the return value might point cannot be converted.

4. Convert any structures referenced by message parameters which might have been modified by the window procedure. Note that the pointer-conversion procedure should ensure that the original memory is still available before converting the structures.

A pointer-conversion procedure should process only those messages that it recognizes. On receiving unrecognized messages, it should set *usmsg* to 0.

WindowDCHook

WindowDCHook - Syntax

This hook is called when a device context is allocated or freed.

```
#define INCL_WINHOOKS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;          /* The application anchor block. */
HDC      hdc;          /* The current device-context handle. */
HWND     hwnd;         /* The current window handle. */
BOOL     flAssociate;  /* Association flag. */
BOOL     rc;           /* Success indicator. */

rc = WindowDCHook(hab, hdc, hwnd, flAssociate);
```

WindowDCHook Parameter - hab

hab (**HAB**) - input
The application anchor block.

WindowDCHook Parameter - hdc

hdc (**HDC**) - input
The current device-context handle.

WindowDCHook Parameter - hwnd

hwnd (**HWND**) - input
The current window handle.

WindowDCHook Parameter - flAssociate

flAssociate (**BOOL**) - input
Association flag.

TRUE	Device context has been allocated.
FALSE	Device context has been freed.

WindowDCHook Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion.
FALSE	Errors occurred.

WindowDCHook - Parameters

hab ([HAB](#)) - input
The application anchor block.

hdc ([HDC](#)) - input
The current device-context handle.

hwnd ([HWND](#)) - input
The current window handle.

flAssociate ([BOOL](#)) - input
Association flag.

TRUE	Device context has been allocated.
FALSE	Device context has been freed.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion.
FALSE	Errors occurred.

WindowDCHook - Topics

Select an item:

- [Syntax](#)

WndProc

WndProc - Syntax

This defines the window procedure provided by an application.

```
#define INCL_WINMESSAGEGR /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HWND      hwnd;      /* Window handle. */
ULONG     msg;        /* Message identity. */
MPARAM    mp1;        /* Message parameter 1. */
MPARAM    mp2;        /* Message parameter 2. */
MRESULT   mresReply;  /* Message-return data. */

mresReply = WndProc(hwnd, msg, mp1, mp2);
```

WndProc Parameter - hwnd

hwnd ([HWND](#)) - input
Window handle.

WndProc Parameter - msg

msg ([ULONG](#)) - input
Message identity.

WndProc Parameter - mp1

mp1 ([MPARAM](#)) - input
Message parameter 1.

WndProc Parameter - mp2

mp2 ([MPARAM](#)) - input
Message parameter 2.

WndProc Return Value - mresReply

mresReply ([HRESULT](#)) - returns
Message-return data.

WndProc - Parameters

hwnd ([HWND](#)) - input

Window handle.

msg ([ULONG](#)) - input
Message identity.

mp1 ([MPARAM](#)) - input
Message parameter 1.

mp2 ([MPARAM](#)) - input
Message parameter 2.

mresReply ([MRESULT](#)) - returns
Message-return data.

WndProc - Remarks

This procedure is associated with a window by the *pfmWndProc* of the [WinRegisterClass](#) function.

The window procedure typically processes only some of the messages passed to it. Those messages it does not process must be passed on to the [WinDefWindowProc](#) function, which performs the standard window processing for those messages.

Profile Functions

This section describes functions that an application would use to query or write user-specific initialization files.

PrfCloseProfile

PrfCloseProfile - Syntax

This function indicates that a profile is no longer available for use.

```
#define INCL_WINSHELLDATA /* Or use INCL_WIN, INCL_PM, */  
#include <os2.h>
```

```
HINI    hini; /* Initialization-file handle. */
BOOL    rc;   /* Success indicator. */

rc = PrfCloseProfile(hini);
```

PrfCloseProfile Parameter - hini

hini (**HINI**) - input
Initialization-file handle.

After this function, the handle is no longer valid.

PrfCloseProfile Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion.
FALSE	Error occurred.

PrfCloseProfile - Parameters

hini (**HINI**) - input
Initialization-file handle.

After this function, the handle is no longer valid.

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion.
FALSE	Error occurred.

PrfCloseProfile - Remarks

This function cannot be used to close the current user or system initialization files.

PrfCloseProfile - Errors

Possible returns from [WinGetLastError](#)

PMERR_INI_FILE_IS_SYS_OR_USER (0x1124)
User or system initialization file cannot be closed.

PMERR_INVALID_INI_FILE_HANDLE (0x1115)
An invalid initialization-file handle was specified.

PrfCloseProfile - Related Functions

Related Functions

- [PrfOpenProfile](#)

PrfCloseProfile - Example Code

This example calls PrfCloseProfile to close a profile after it has been used.

```
/* Write and read binary data to a profile.  Some return code */
/* checking omitted for brevity.                               */

#define INCL_WINSHELLDATA
#define INCL_WINERRORS
#define INCL_DOSERRORS
#include <os2.h>
#include <stdio.h>
#include <string.h>

#define BUFSIZE 7

PrfOpenProfile

PrfOpenProfile - Syntax

This function indicates that a file is available for use as a profile.

```
#define INCL_WINSHELLDATA /* Or use INCL_WIN, INCL_PM, */
```

```
#include <os2.h>

HAB      hab;           /* Anchor-block handle. */
PSZ      pszFileName;   /* User-profile file name. */
HINI     hini;          /* Initialization-file handle. */

hini = PrfOpenProfile(hab, pszFileName);
```

PrfOpenProfile Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

PrfOpenProfile Parameter - pszFileName

pszFileName ([PSZ](#)) - input
User-profile file name.

This must not be the same as the current user (OS2.INI) or system initialization (OS2SYS.INI) file name.

PrfOpenProfile Return Value - hini

hini ([HINI](#)) - returns
Initialization-file handle.

This handle is used on other calls to manipulate the profile file.

NULLHANDLE	Error occurred
Other	Initialization-file handle.

PrfOpenProfile - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

pszFileName ([PSZ](#)) - input
User-profile file name.

This must not be the same as the current user (OS2.INI) or system initialization (OS2SYS.INI) file name.

hini ([HINI](#)) - returns

Initialization-file handle.

This handle is used on other calls to manipulate the profile file.

NULLHANDLE

Error occurred

Other

Initialization-file handle.

PrfOpenProfile - Remarks

A user profile and a system profile are opened by the system, either at start-up time, or (in the case of the user profile) as a result of a [PrfReset](#) function, and are always available. Their handles are HINI_USERPROFILE and HINI_SYSTEMPROFILE. Applications do not have to open or close the user profile or the system profile.

The handle returned is only valid for the process issuing the PrfOpenProfile function.

The PrfOpenProfile function can be used by an administrator's application that is creating or modifying a profile for a user.

It can also be used to create a back-up profile as follows:

- Use the enumerate form of [PrfQueryProfileData](#) to obtain a list of application names in the profile being backed up.
- Use the enumerate form of [PrfQueryProfileData](#) to obtain a list of key names for each of the application names.
- Use [PrfQueryProfileData](#) for each application-name or key-name pair to read the appropriate data.
- Use [PrfWriteProfileData](#) to write the data into the back-up profile.

PrfOpenProfile - Errors

Possible returns from [WinGetLastError](#)

PMERR_OPENING_INI_FILE (0x1301)

Unable to open initialization file (due to lack of disk space for example).

PMERR_MEMORY_ALLOC (0x1309)

An error occurred during memory management.

PMERR_INI_FILE_IS_SYS_OR_USER (0x1124)

User or system initialization file cannot be closed.

PrfQueryProfile

PrfQueryProfile - Syntax

This function returns a description of the current user and system profiles.

```
#define INCL_WINSHELLDATA /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB hab;          /* Anchor-block handle. */
PPRFPROFILE pprfproProfile; /* Profile names structure. */
BOOL rc;          /* Success indicator. */

rc = PrfQueryProfile(hab, pprfproProfile);
```

PrfQueryProfile Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

PrfQueryProfile Parameter - pprfproProfile

pprfproProfile ([PPRFPROFILE](#)) - in/out
Profile names structure.

The parameters of the [PPRFPROFILE](#) data structure are set to the lengths of the respective file names, even if truncation occurs. If these fields are initialized to 0 by the application, then the parameters are not inspected, and the application can then determine the sizes of the buffers required to hold the names on a second call. Otherwise, the parameters must point to reserved areas of memory, and the parameters must indicate the sizes of those areas.

If the parameter is NULL, then there is no defined user or system profile, respectively.

PrfQueryProfile Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred, or there was insufficient space to record the names, which have been truncated.

PrfQueryProfile - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

pprfproProfile ([PPRFPROFILE](#)) - in/out
Profile names structure.

The parameters of the [PPRFPROFILE](#) data structure are set to the lengths of the respective file names, even if truncation occurs. If these fields are initialized to 0 by the application, then the parameters are not inspected, and the application can then determine the sizes of the buffers required to hold the names on a second call. PrfQueryProfileData

PrfQueryProfileData - Syntax

This function returns a string of binary data from the specified profile.

```
#define INCL_WINSHELLDATA /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HINI      hini;          /* Initialization-file handle. */
PSZ       pszApp;        /* Application name. */
PSZ       pszKey;        /* Key name. */
PVOID     pBuffer;       /* Value data. */
PULONG    pBufferMax;    /* Size of value data. */
BOOL      rc;            /* Success indicator. */

rc = PrfQueryProfileData(hini, pszApp, pszKey,
                        pBuffer, pBufferMax);
```

PrfQueryProfileData Parameter - hini

hini (**HINI**) - input
Initialization-file handle.

HINI_PROFILE	Both the user profile and system profile are searched
HINI_USERPROFILE	The user profile is searched
HINI_SYSTEMPROFILE	The system profile is searched
Other	Initialization-file handle.

PrfQueryProfileData Parameter - pszApp

pszApp (**PSZ**) - input
Application name.

The name of the application for which the profile data is required. The name must match exactly with the name stored in the profile. There is no case-independent searching.

If this parameter is NULL, this function enumerates all the application names present in the profile and returns the names as a list in the *pBuffer* parameter. Each application name is terminated with a NULL character and the last name is terminated with two successive NULL characters. In this case, the *pBufferMax* parameter contains the total length of the list excluding the final NULL character.

PrfQueryProfileData Parameter - pszKey

pszKey (**PSZ**) - input
Key name.

The name of the key for which the profile data is required. The name must match exactly with the name stored in the profile. There is

no case-independent searching.

If this parameter is NULL, and if *pszApp* is not equal to NULL, this call enumerates all key names associated with the named application and returns the key names, but not their values, as a list in the *pBuffer* parameter. Each key name is terminated with a NULL character and the last name is terminated with two successive NULL characters. In this case, the *pulBufferMax* parameter contains the total length of the list **excluding** the final NULL character.

PrfQueryProfileData Parameter - pBuffer

pBuffer (**PVOID**) - output
Value data.

A buffer in which the value corresponding to the key name is returned. The returned data is not null terminated, unless the value data is explicitly null terminated within the file. This function handles binary data.

PrfQueryProfileData Parameter - pulBufferMax

pulBufferMax (**PULONG**) - in/out
Size of value data.

This is the size of the buffer specified by the *pBuffer* parameter. If the call is successful, this is overwritten with the number of bytes copied into the buffer. The maximum amount of data that can be returned is 64K bytes.

PrfQueryProfileData Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

PrfQueryProfileData - Parameters

hini (**HINI**) - input
Initialization-file handle.

HINI_PROFILE	Both the user profile and system profile are searched
HINI_USERPROFILE	The user profile is searched
HINI_SYSTEMPROFILE	The system profile is searched

Other

Initialization-file handle.

pszApp ([PSZ](#)) - input
Application name.

The name of the application for which the profile data is required. The name must match exactly with the name stored in the profile. There is no case-independent searching.

If this parameter is NULL, this function enumerates all the application names present in the profile and returns the names as a list in the *pBuffer* parameter. Each application name is terminated with a NULL character and the last name is terminated with two successive NULL characters. In this case, the *pulBufferMax* parameter contains the total length of the list excluding the final NULL character.

pszKey ([PSZ](#)) - input
Key name.

The name of the key for which the profile data is required. The name must match exactly with the name stored in the profile. There is no case-independent searching.

If this parameter is NULL, and if *pszApp* is not equal to NULL, this call enumerates all key names associated with the named application and returns the key names, but not their values, as a list in the *pBuffer* parameter. Each key name is terminated with a NULL character and the last name is terminated with two successive NULL characters. In this case, the *pulBufferMax* parameter contains the total length of the list **excluding** the final NULL character.

pBuffer ([PVOID](#)) - output
Value data.

A buffer in which the value corresponding to the key name is returned. The returned data is not null terminated, unless the value data is explicitly null terminated within the file. This function handles binary data.

pulBufferMax ([PULONG](#)) - in/out
Size of value data.

This is the size of the buffer specified by the *pBuffer* parameter. If the call is successful, this is overwritten with the number of bytes copied into the buffer. The maximum amount of data that can be returned is 64K bytes.

rc ([BOOL](#)) - returns
Success indicator.

TRUE

Successful completion

FALSE

Error occurred.

PrfQueryProfileData - Remarks

This function returns a string of binary data from the profile. The call searches the file for a key matching the name specified by the *pszKey* parameter, under the application heading specified by the *pszApp* parameter.

Enumeration can be performed in exactly the same way as in the [PrfQueryProfileString](#) function. The enumeration returns application or key names irrespective of whether the data concerned is written with the [PrfWriteProfileString](#) function or the [PrfWriteProfileData](#) function.

This function returns data that is written to the file using either the [PrfWriteProfileString](#) function or the [PrfWriteProfileData](#) function.

If the *pszApp* parameter is NULL, this call enumerates all application names and constructs in the *pBuffer* parameter a list of application names. Each application name in the list is terminated with a null character. The last string in the list is terminated with two null characters. This function returns the length of the list, up to, but not including, the final null. If the enumerated application names exceed the available buffer space, the enumerated names are truncated, the enumerated list is not terminated with 2 bytes of zeros, and the *rc* parameter is set to FALSE. In this case, *pszKey* is ignored.

If the *pszApp* parameter is valid and if the *pszKey* is NULL, this function enumerates all key names associated with the *pszApp* parameter by constructing in the *pBuffer* parameter a list of key names. Each key name in the list is terminated with a null character. The last string in the list is terminated with two null characters. This function returns the length of the list, up to, but not including, the final null.

If the enumerated key names exceed the available buffer space, the enumerated names are truncated, the enumerated list is not terminated

with 2 bytes of zeros, and the `/c` parameter is set to FALSE.

The maximum size of data that can be associated with a key name is 64K bytes.

PrfQueryProfileData - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_PARM (0x1303)

A parameter to the function contained invalid data.

PMERR_NOT_IN_IDX (0x1304)

The application name, key-name or program handle was not found.

PMERR_CAN_NOT_CALL_SPOOLER (0x130D)

An error occurred attempting to call the spooler validation routine. This error is not raised if the spooler is not installed.

PrfQueryProfileInt

PrfQueryProfileInt - Syntax

This function returns an integer value from the specified profile.

```
#define INCL_WINSHELLDATA /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HINI    hini;        /* Initialization-file handle. */
PSZ     pszApp;      /* Application name. */
PSZ     pszKey;       /* Key name. */
LONG    lDefault;     /* Default value. */
LONG    lResult;      /* Key value specified in the initialization file. */

lResult = PrfQueryProfileInt(hini, pszApp,
                             pszKey, lDefault);
```

PrfQueryProfileInt Parameter - hini

hini ([HINI](#)) - input

Initialization-file handle.

HINI_PROFILE

Both the user profile and system profile are searched

HINI_USERPROFILE

The user profile is searched

HINI_SYSTEMPROFILE

The system profile is searched

Other

Initialization-file handle returned by [PrfOpenProfile](#).

PrfQueryProfileInt Parameter - pszApp

pszApp ([PSZ](#)) - input

Application name.

The name of the application for which the profile data is required. The name must match exactly with the name stored in the profile. There is no case-independent searching.

PrfQueryProfileInt Parameter - pszKey

pszKey ([PSZ](#)) - input

Key name.

The name of the key for which the profile data is required. The name must match exactly with the name stored in the profile. There is no case-independent searching.

PrfQueryProfileInt Parameter - IDefault

IDefault ([LONG](#)) - input
Default value.

This value is returned in *//Result*, if the key defined by *pszKey* cannot be found in the initialization file.

PrfQueryProfileInt Return Value - IResult

IResult ([LONG](#)) - returns
Key value specified in the initialization file.

The value of the key specified by *pszKey* in the initialization file.

If the value corresponding to the key is not an integer, *//Result* is 0.

If the key-name value is a series of digits followed by non-numeric characters, *//Result* contains the value of the digits only. For example, "KeyName=102abc" causes the value 102 to appear in *//Result*.

PrfQueryProfileInt - Parameters

hini ([HINI](#)) - input
Initialization-file handle.

HINI_PROFILE	Both the user profile and system profile are searched
HINI_USERPROFILE	The user profile is searched
HINI_SYSTEMPROFILE	The system profile is searched
Other	Initialization-file handle returned by PrfOpenProfile .

pszApp ([PSZ](#)) - input
Application name.

The name of the application for which the profile data is required. The name must match exactly with the name stored in the profile. There is no case-independent searching.

pszKey ([PSZ](#)) - input
Key name.

The name of the key for which the profile data is required. The name must match exactly with the name stored in the profile. There is no case-independent searching.

IDefault ([LONG](#)) - input
Default value.

This value is returned in *//Result*, if the key defined by *pszKey* cannot be found in the initialization file.

IResult ([LONG](#)) - returns

Key value specified in the initialization file.

The value of the key specified by *pszKey* in the initialization file.

If the value corresponding to the key is not an integer, *IResult* is 0.

If the key-name value is a series of digits followed by non-numeric characters, *IResult* contains the value of the digits only. For example, "KeyName=102abc" causes the value 102 to appear in *IResult*.

PrfQueryProfileInt - Remarks

This function returns an integer value from the profile. The call searches the file for a key matching the name specified by the *pszKey* parameter, under the application heading specified by the *pszApp* parameter. When an integer is stored as a text string using the [PrfWriteProfileString](#) function, for example,

```
PrfWriteProfileString(HINI_PROFILE,
                    app, key,
                    _itoa(123,string,radix));
```

the returned value is the number, 123. When querying an INI file for values, the string in the INI file must be NULL terminated for consistent and correct results. The call returns *Default* if the application-name or key-name pair cannot be found.

Note: The search is case-dependent.

PrfQueryProfileInt - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_PARM (0x1303)

A parameter to the function contained invalid data.

PMERR_NOT_IN_IDX (0x1304)

The application name, key-name or program handle was not found.

PMERR_CAN_NOT_CALL_SPOOLER (0x130D)

An error occurred attempting to call the spooler validation routine. This error is not raised if the spooler is not installed.

```
#define INCL_WINSHELLDATA /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HINI      hini;          /* Initialization-file handle. */
PSZ       pszApp;        /* Application name. */
PSZ       pszKey;        /* Key name. */
PULONG    pulDataLen;    /* Data length. */
BOOL      rc;            /* Success indicator. */

rc = PrfQueryProfileSize(hini, pszApp, pszKey,
                        pulDataLen);
```

PrfQueryProfileSize Parameter - hini

hini ([HINI](#)) - input
Initialization-file handle.

HINI_PROFILE	Both the user profile and system profile are searched
HINI_USERPROFILE	The user profile is searched
HINI_SYSTEMPROFILE	The system profile is searched
Other	Initialization-file handle returned by PrfOpenProfile .

PrfQueryProfileSize Parameter - pszApp

pszApp ([PSZ](#)) - input
Application name.

The name of the application for which the profile data is required.

If the *pszApp* parameter is NULL, then the *pulDataLen* parameter returns the length of the buffer required to hold the enumerated list of application names, as returned by the [PrfQueryProfileString](#) function when its *pszApp* parameter is NULL. In this case, the

pszKey parameter is ignored.

PrfQueryProfileSize Parameter - pszKey

pszKey (**PSZ**) - input
Key name.

The name of the key for which the size of the data is to be returned.

If the *pszKey* parameter is NULL, and if the *pszApp* parameter is not NULL, the *pulDataLen* returns the length of the buffer required to hold the enumerated list of key names for that application name, as returned by the [PrfQueryProfileString](#) function when its *pszKey* parameter is NULL, and its *pszApp* parameter is not NULL.

PrfQueryProfileSize Parameter - pulDataLen

pulDataLen (**PULONG**) - output
Data length.

This parameter is the length of the value data related to the *pszKey* parameter. If an error occurs, this parameter is undefined. The maximum size of data than can be returned is 64K bytes.

PrfQueryProfileSize Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

PrfQueryProfileSize - Parameters

hini (**HINI**) - input
Initialization-file handle.

HINI_PROFILE	Both the user profile and system profile are searched
HINI_USERPROFILE	The user profile is searched
HINI_SYSTEMPROFILE	The system profile is searched
Other	Initialization-file handle returned by PrfOpenProfile .

pszApp (PSZ) - input
Application name.

The name of the application for which the profile data is required.

If the *pszApp* parameter is NULL, then the *pulDataLen* parameter returns the length of the buffer required to hold the enumerated list of application names, as returned by the [PrfQueryProfileString](#) function when its *pszApp* parameter is NULL. In this case, the *pszKey* parameter is ignored.

pszKey (PSZ) - input
Key name.

The name of the key for which the size of the data is to be returned.

If the *pszKey* parameter is NULL, and if the *pszApp* parameter is not NULL, the *pulDataLen* returns the length of the buffer required to hold the enumerated list of key names for that application name, as returned by the [PrfQueryProfileString](#) function when its *pszKey* parameter is NULL, and its *pszApp* parameter is not NULL.

pulDataLen (PULONG) - output
Data length.

This parameter is the length of the value data related to the *pszKey* parameter. If an error occurs, this parameter is undefined. The maximum size of data than can be returned is 64K bytes.

rc (BOOL) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

PrfQueryProfileSize - Remarks

The *pszApp* parameter and *pszKey* parameter are case sensitive and must match the names stored in the file exactly. There is no case-independent searching.

This function can be used before using the [PrfQueryProfileString](#) call or the [PrfQueryProfileData](#) call, to allocate space for the returned data.

No distinction is made between data that is written using the [PrfWriteProfileData](#) function and the [PrfWriteProfileString](#) function.

The maximum amount of data that can be associated with a key name is 64K bytes.

PrfQueryProfileSize - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_PARM (0x1303)
A parameter to the function contained invalid data.

PMERR_NOT_IN_IDX (0x1304)
The application name, key-name or program handle was not found.

PMERR_CAN_NOT_CALL_SPOOLER (0x130D)
An error occurred attempting to call the spooler validation routine. This error is not raised if the spooler is not installed.

PrfQueryProfileSize - Example Code

This example calls PrfQueryProfileSize to search the user and system profiles for the value of key "KEY" within the application "APP" and return the byte size of the value if found.

```
#define INCL_WINSHELLDATA      /* Window Shell functions */
#include <os2.h>

BOOL fSuccess;                /* success indicator */
HINI hini;                    /* initialization-file handle */
char pszApp[10];              /* application name */
char pszKey[10];              /* key name */
ULONG pDataLen;              /* data length */

/* Both the user profile and system profile are searched */
hini = HINI_PROFILE;

/* specify application and key names */
strcpy(pszApp, "APP");
strcpy(pszKey, "KEY");

fSuccess = PrfQueryProfileSize(hini, pszApp, pszKey, &pDataLen);
```

PrfQueryProfileString

PrfQueryProfileString - Syntax

This function retrieves a string from the specified profile. This function is designed to search data written with [PrfWriteProfileString](#)

```

#define INCL_WINSHELLDATA /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HINI      hini;           /* Initialization-file handle. */
PSZ       pszApp;         /* Application name. */
PSZ       pszKey;         /* Key name. */
PSZ       pszDefault;     /* Default string. */
PVOID     pBuffer;        /* Profile string. */
ULONG     ulBufferMax;    /* Maximum string length. */
ULONG     ulLength;       /* String length returned. */

ulLength = PrfQueryProfileString(hini, pszApp,
                                pszKey, pszDefault, pBuffer,
                                ulBufferMax);

```

PrfQueryProfileString Parameter - hini

hini (**HINI**) - input
Initialization-file handle.

HINI_PROFILE	Both the user profile and system profile are searched
HINI_USERPROFILE	The user profile is searched
HINI_SYSTEMPROFILE	The system profile is searched
Other	Initialization-file handle returned by the PrfOpenProfile function.

PrfQueryProfileString Parameter - pszApp

pszApp (**PSZ**) - input
Application name.

The name of the application for which the profile data is required.

The search performed on the application name is always case-dependent. Names starting with the characters "PM_" are reserved for system use.

If this parameter is NULL, this function enumerates all the application names present in the profile and returns the names as a list in the *pBuffer* parameter. Each application name is terminated with a NULL character and the last name is terminated with two successive NULL characters. In this instance, the *ulLength* parameter contains the total length of the list **excluding** the final NULL character.

PrfQueryProfileString Parameter - pszKey

pszKey (**PSZ**) - input
Key name.

The name of the key for which the profile data is returned.

The search on key name is always case-dependent.

If this parameter equals NULL, and if the *pszApp* parameter is not equal to NULL, this function enumerates all key names associated with the named application and returns the key names (not their values) as a list in the *pBuffer* parameter. Each key name is terminated with a NULL character and the last name is terminated with two successive NULL characters. In this instance, the *ulLength* parameter contains the total length of the list **excluding** the final NULL character.

PrfQueryProfileString Parameter - pszDefault

pszDefault (**PSZ**) - input
Default string.

The string that is returned in the *pBuffer* parameter, if the key defined by the *pszKey* parameter cannot be found in the profile.

If the pointer to this parameter is passed as NULL, then nothing is copied into the *pszKey* parameter if the key cannot be found. *ulLength* is returned as 0 in this case.

PrfQueryProfileString Parameter - pBuffer

pBuffer (**PVOID**) - output
Profile string.

The text string obtained from the profile for the key defined by the *pszKey* parameter.

PrfQueryProfileString Parameter - ulBufferMax

ulBufferMax (**ULONG**) - input
Maximum string length.

The maximum number of characters that can be put into the *pBuffer* parameter, in bytes. If the data from the profile is longer than this, it is truncated.

PrfQueryProfileString Return Value - ulLength

ulLength (**ULONG**) - returns
String length returned.

The actual number of characters (including the null termination character) returned in the *pBuffer* parameter, in bytes.

PrfQueryProfileString - Parameters

hini (**HINI**) - input
Initialization-file handle.

HINI_PROFILE
Both the user profile and system profile are searched
HINI_USERPROFILE
The user profile is searched
HINI_SYSTEMPROFILE
The system profile is searched
Other
Initialization-file handle returned by the PrfOpenProfile function.

pszApp (**PSZ**) - input
Application name.

The name of the application for which the profile data is required.

The search performed on the application name is always case-dependent. Names starting with the characters "PM_" are reserved for system use.

If this parameter is NULL, this function enumerates all the application names present in the profile and returns the names as a list in the *pBuffer* parameter. Each application name is terminated with a NULL character and the last name is terminated with two successive NULL characters. In this instance, the *ulLength* parameter contains the total length of the list **excluding** the final NULL character.

pszKey (**PSZ**) - input
Key name.

The name of the key for which the profile data is returned.

The search on key name is always case-dependent.

If this parameter equals NULL, and if the *pszApp* parameter is not equal to NULL, this function enumerates all key names associated with the named application and returns the key names (not their values) as a list in the *pBuffer* parameter. Each key name is terminated with a NULL character and the last name is terminated with two successive NULL characters. In this instance, the *ulLength* parameter contains the total length of the list **excluding** the final NULL character.

pszDefault (**PSZ**) - input
Default string.

The string that is returned in the *pBuffer* parameter, if the key defined by the *pszKey* parameter cannot be found in the profile.

If the pointer to this parameter is passed as NULL, then nothing is copied into the *pszKey* parameter if the key cannot be found. *ulLength* is returned as 0 in this case.

pBuffer (**PVOID**) - output
Profile string.

The text string obtained from the profile for the key defined by the *pszKey* parameter.

ulBufferMax (**ULONG**) - input
Maximum string length.

The maximum number of characters that can be put into the *pBuffer* parameter, in bytes. If the data from the profile is longer than this, it is truncated.

ulLength (**ULONG**) - returns
String length returned.

The actual number of characters (including the null termination character) returned in the *pBuffer* parameter, in bytes.

PrfQueryProfileString - Remarks

The call searches the profile for a key matching the name specified by the *pszKey* parameter under the application heading specified by the *pszApp* parameter. If the key is found, the corresponding string is copied. If the key does not exist, the default character string, specified by the *pszDefault* parameter, is copied.

If the enumerated application names exceed the available buffer space, the enumerated names are truncated, the enumerated list is not terminated with 2 bytes of zeros, and the *ulLength* parameter is set to the number of bytes copied into the *pBuffer* parameter. In this instance, the *pszKey* parameter is ignored.

Note: If the enumeration cannot be performed for any reason, the default character string is *not* copied.

This function returns the length of the list, up to, but not including, the final null. If the enumerated key names exceed the available buffer space, the enumerated names are truncated, the enumerated list is not terminated with 2 bytes of zeros, and the *ulLength* parameter is set to the number of bytes copied into the *pBuffer* parameter.

This function is case-dependent; thus the strings in the *pszApp* parameter and the *pszKey* parameter must match exactly. This avoids any code-page dependency. The application storing the data must do any case-independent matching.

The enumeration call does not distinguish between data written with the [PrfWriteProfileString](#) function and the [PrfWriteProfileData](#) function.

PrfQueryProfileString - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_PARM (0x1303)

A parameter to the function contained invalid data.

PMERR_BUFFER_TOO_SMALL (0x110B)

The supplied buffer was not large enough for the data to be returned.

PMERR_NOT_IN_IDX (0x1304)

The application name, key-name or program handle was not found.

PMERR_CAN_NOT_CALL_SPOOLER (0x130D)

An error occurred attempting to call the spooler validation routine. This error is not raised if the spooler is not installed.

PMERR_INVALID_ASCII (0x130C)

The profile string is not a valid zero-terminated string.

PrfQueryProfileString - Example Code

PrfQueryProfileString is issued twice to obtain the names of the default printer, the default presentation driver, and the queue associated with the printer. If any of these requests fails, the default values already defined in DEVOPENSTRUC are used.

```
#define INCL_WINSHELLDATA
#include <OS2.H>
char szTemp[80];
char szBuff[257];
```

```

PCH ptscan;

DEVOPENSTRUC dopPrinter = {"LPT1Q",
    (PSZ)"IBM4201",
    0L,
    (PSZ)"PM_Q_STD",
    0L, 0L, 0L, 0L, 0L};

if (PrfQueryProfileString(HINI_PROFILE,
    (PSZ)"PM_SPOOLER",
    (PSZ)"PRINTER",
    NULL,
    (PVOID)szTemp,
    (LONG)sizeof(szTemp)
    )){
    szTemp[strlen(szTemp)-1] = 0;
    if (PrfQueryProfileString(HINI_PROFILE,
        (PSZ)"PM_SPOOLER_PRINTER",
        (PSZ)szTemp,
        NULL,
        (PVOID)szBuff,
        (LONG)sizeof(szBuff)
        )){

        ptscan = (PCH)strchr(szBuff, ';');
        ptscan++;
        ptscan = (PCH)strchr(ptscan, (INT)';');
        ptscan++;
        *(ptscan + strcspn(ptscan, ".,;")) = 0;
        dopPrinter.pszLogAddress = ptscan;

        ptscan = (PCH)strchr(szBuff, (INT)';');
        ptscan++;
        *(ptscan + strcspn(ptscan, ".,;")) = 0;
        dopPrinter.pszDriverName = ptscan;

    }
}

```

PrfReset

PrfReset - Syntax

This function defines which files are to be used as the user and system profiles.

```
#define INCL_WINSHELLDATA /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
PPRFPROFILE pPrfProfile; /* Profile-names structure. */
BOOL      rc;          /* Success indicator. */

rc = PrfReset(hab, pPrfProfile);
```

PrfReset Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

PrfReset Parameter - pPrfProfile

pPrfProfile ([PPRFPROFILE](#)) - input
Profile-names structure.

This contains the names of the files to be used as the new Presentation Manager* (PM*) profile files. Any valid file names can be used. A name that is not already fully qualified is taken to refer to the current directory.

If the user profile file does not exist, a new file is created.

The name of the system profile cannot be changed. It must be the name of the current system profile as returned by [PrfQueryProfile](#).

PrfReset Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

PrfReset - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

pPrfProfile ([PPRFPROFILE](#)) - input
Profile-names structure.

This contains the names of the files to be used as the new Presentation Manager* (PM*) profile files. Any valid file names can be used. A name that is not already fully qualified is taken to refer to the current directory.

If the user profile file does not exist, a new file is created.

The name of the system profile cannot be changed. It must be the name of the current system profile as returned by [PrfQueryProfile](#).

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

PrfReset - Remarks

This function causes the workstation to use different profiles. When the workstation is initialized, the names of the user and system profiles are taken from the PROTSHELL statement specified in CONFIG.SYS. PrfReset allows the profiles to be changed during operation of the workstation, for example by a logon application controlling multiple consecutive users of the system.

After the PrfReset function completes, the system has a new set of preferences (for example screen colors), a new start-up list, and new spooler parameters.

The PrfReset function broadcasts the [PL_ALTERED](#) message, which must be processed by all applications that read their default settings from the user or system profiles.

Note: This will only change the default system values in the ini file. It is up to the applications to read the new default settings and reset them to their new values.

For example, consider logon applications. On receipt of a [PL_ALTERED](#) message, they should carry out the following:

- Read the new color settings from the new profiles, and set the new screen colors (and palettes) which should be refreshed.
- Set the country information, for example the date and time format, which is read from the new profiles.
- Other preferences, for example, those that affect the operations of the alarm and the mouse, should also update with the new settings held in the new profiles.

This function requires the existence of a message queue.

PrfReset - Errors

Possible returns from [WinGetLastError](#)

PMERR_OPENING_INI_FILE (0x1301)
Unable to open initialization file (due to lack of disk space for example).

PrfWriteProfileData

PrfWriteProfileData - Syntax

This function writes a string of binary data into the specified profile.

```
#define INCL_WINSHELLDATA /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HINI    hini;        /* Initialization-file handle. */
PSZ     pszApp;      /* Application name. */
PSZ     pszKey;      /* Key name. */
PVOID   pData;       /* Value data. */
ULONG   ulDataLen;   /* Size of value data. */
BOOL    rc;          /* Success indicator. */

rc = PrfWriteProfileData(hini, pszApp, pszKey,
    pData, ulDataLen);
```

PrfWriteProfileData Parameter - hini

hini ([HINI](#)) - input

Initialization-file handle.

HINI_PROFILE

User profile

HINI_USERPROFILE

User profile

HINI_SYSTEMPROFILE

System profile

Other

Initialization-file handle returned by [PrfOpenProfile](#).

PrfWriteProfileData Parameter - pszApp

pszApp ([PSZ](#)) - input

Application name.

The case-dependent name of the application for which profile data is to be written. Names starting with the characters "PM_" are reserved for system use.

PrfWriteProfileData Parameter - pszKey

pszKey ([PSZ](#)) - input

Key name.

The case-dependent name of the key for which profile data is to be written.

This parameter can be NULL in which case *all* the *pszKey* or *pData* pairs associated with *pszApp* are deleted.

PrfWriteProfileData Parameter - pData

pData ([PVOID](#)) - input
Value data.

This is the value of the *pszKey* or *pData* pair that is written to the profile. It is *not* zero-terminated, and its length is given by the *ulDataLen* parameter.

If this parameter is NULL, the string associated with the *pszKey* parameter is deleted.

PrfWriteProfileData Parameter - ulDataLen

ulDataLen ([ULONG](#)) - input
Size of value data.

The size of the data to be written. This length should not exceed 64K bytes.

PrfWriteProfileData Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

PrfWriteProfileData - Parameters

hIni ([HINI](#)) - input
Initialization-file handle.

HINI_PROFILE	User profile
HINI_USERPROFILE	User profile
HINI_SYSTEMPROFILE	System profile
Other	Initialization-file handle returned by PrfOpenProfile .

pszApp ([PSZ](#)) - input
Application name.

The case-dependent name of the application for which profile data is to be written. Names starting with the characters "PM_" are reserved for system use.

pszKey ([PSZ](#)) - input
Key name.

The case-dependent name of the key for which profile data is to be written.

This parameter can be NULL in which case *all* the *pszKey* or *pData* pairs associated with *pszApp* are deleted.

pData ([PVOID](#)) - input
Value data.

This is the value of the *pszKey* or *pData* pair that is written to the profile. It is *not* zero-terminated, and its length is given by the *ulDataLen* parameter.

If this parameter is NULL, the data associated with the *pszKey* parameter is deleted.

ulDataLen ([ULONG](#)) - input
Size of value data.

The size of the data to be written. This length should not exceed 64K bytes.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

PrfWriteProfileData - Remarks

If there is no application field in the file that matches the *pszApp*, a new application field is created before the *pszKey* or *pszData* entry is made.

If the key name does not exist for the application, a new *pszKey* or *pszData* entry is created for that application. If the *pszKey* already exists in the file, the existing value is overwritten.

Because of the binary nature of the data, the input data is not zero-terminated. Thus, the length provided is the only way to identify the length of the data.

The maximum size of data that can be associated with a key name is 64K bytes. Data in excess of 64K bytes may be written, but there is no mechanism for retrieving all the data.

Deleting Profile Information

To remove the data associated with a given *pszKey* value for an application, specify a NULL value for *pData* and a zero length in *ulDataLen*.

To remove all the data associated with a particular application, use a *pszKey* value of NULL, a *pData* value of NULL, and a *ulDataLen* value of 0.

To remove **ALL** the data in a user profile, set *pszName*, *pszKey*, and *pData* to NULL, and set *ulDataLen* to zero.

PrfWriteProfileData - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_PARM (0x1303)
A parameter to the function contained invalid data.

PMERR_CAN_NOT_CALL_SPOOLER (0x130D)

An error occurred attempting to call the spooler validation routine. This error is not raised if the spooler is not installed.

PrfWriteProfileString

PrfWriteProfileString - Syntax

This function writes a string of character data into the specified profile.

```

#define INCL_WINSHELLDATA /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HINI    hini;      /* Initialization-file handle. */
PSZ     pszApp;    /* Application name. */
PSZ     pszKey;    /* Key name. */
PSZ     pszData;   /* Text string. */
BOOL    rc;        /* Success indicator. */

rc = PrfWriteProfileString(hini, pszApp, pszKey,
                           pszData);

```

PrfWriteProfileString Parameter - hini

hini ([HINI](#)) - input

Initialization-file handle.

HINI_PROFILE

User profile

HINI_USERPROFILE

User profile

HINI_SYSTEMPROFILE

System profile

Other

Initialization-file handle returned by [PrfOpenProfile](#).

PrfWriteProfileString Parameter - pszApp

pszApp ([PSZ](#)) - input

Application name.

The case-dependent name of the application for which profile data is to be written. Names starting with the characters "PM_" are reserved for system use.

PrfWriteProfileString Parameter - pszKey

pszKey ([PSZ](#)) - input

Key name.

The case-dependent name of the key for which profile data is to be written.

This parameter can be NULL, in which case *all* the *pszKey* or *pszData* pairs associated with the *pszApp* parameter are deleted.

PrfWriteProfileString Parameter - pszData

pszData ([PSZ](#)) - input

Text string.

This is the value of the *pszKey* or *pszData* pair that is written to the profile.

If this parameter is NULL, the string associated with the *pszKey* is deleted (that is, the entry is deleted).

If this parameter is not NULL, the string is used as the value of the *pszKey* or *pszData* pair, even if the string has zero length.

PrfWriteProfileString Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

PrfWriteProfileString - Parameters

hini ([HINI](#)) - input
Initialization-file handle.

HINI_PROFILE	User profile
HINI_USERPROFILE	User profile
HINI_SYSTEMPROFILE	System profile
Other	Initialization-file handle returned by PrfOpenProfile .

pszApp ([PSZ](#)) - input
Application name.

The case-dependent name of the application for which profile data is to be written. Names starting with the characters "PM_" are reserved for system use.

pszKey ([PSZ](#)) - input
Key name.

The case-dependent name of the key for which profile data is to be written.

This parameter can be NULL, in which case *all* the *pszKey* or *pszData* pairs associated with the *pszApp* parameter are deleted.

pszData ([PSZ](#)) - input
Text string.

This is the value of the *pszKey* or *pszData* pair that is written to the profile.

If this parameter is NULL, the string associated with the *pszKey* is deleted (that is, the entry is deleted).

If this parameter is not NULL, the string is used as the value of the *pszKey* or *pszData* pair, even if the string has zero length.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

PrfWriteProfileString - Remarks

If there is no application field in the file that matches the *pszApp*, a new application field is created before the *pszKey* or *pszData* entry is made.

If the key name does not exist for the application, a new *pszKey* or *pszData* entry is created for that application. If the *pszKey* already exists in the file, the existing value is overwritten.

PrfWriteProfileString - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_PARM (0x1303)

A parameter to the function contained invalid data.

PMERR_CAN_NOT_CALL_SPOOLER (0x130D)

An error occurred attempting to call the spooler validation routine. This error is not raised if the spooler is not installed.

Spooler Functions

This section describes functions that an application would use to write data directly to a spool file.

SplControlDevice

SplControlDevice - Syntax

This function cancels, holds, continues, or restarts a print device.

```
#define INCL_SPL /* Or use INCL_PM, */
#include <os2.h>

PSZ      pszComputerName; /* Name of computer where print device is to be controlled. */
PSZ      pszPortName;     /* Port name. */
ULONG    ulControl;        /* Operation to perform. */
SPLERR   rc;               /* Return code. */

rc = SplControlDevice(pszComputerName, pszPortName,
                     ulControl);
```

SplControlDevice Parameter - pszComputerName

pszComputerName ([PSZ](#)) - input
Name of computer where print device is to be controlled.

A NULL string specifies the local workstation.

SplControlDevice Parameter - pszPortName

pszPortName ([PSZ](#)) - input
Port name.

SplControlDevice Parameter - ulControl

ulControl ([ULONG](#)) - input
Operation to perform.

PRD_DELETE	Delete current print job
PRD_PAUSE	Pause printing
PRD_CONT	Continue paused print job
PRD_RESTART	Restart print job.

SplControlDevice Return Value - rc

rc (**SPLERR**) - returns

Return code.

NO_ERROR (0)

No errors occurred.

ERROR_NOT_SUPPORTED (50)

This request is not supported by the network.

ERROR_BAD_NETPATH (53)

The network path cannot be located.

NERR_NetNotStarted (2102)

The network program is not started.

NERR_DestNotFound (2152)

The print device cannot be found.

NERR_DestIdle (2158)

This print device is idle and cannot accept control operations.

NERR_DestInvalidOp (2159)

This print device request contains an invalid control function.

NERR_ProcNoRespond (2160)

The queue processor is not responding.

NERR_SpoolerNotLoaded (2161)

The spooler is not running.

NERR_InvalidComputer (2351)

The computer name is invalid.

SplControlDevice - Parameters

pszComputerName (**PSZ**) - input

Name of computer where print device is to be controlled.

A NULL string specifies the local workstation.

pszPortName (**PSZ**) - input

Port name.

ulControl (**ULONG**) - input

Operation to perform.

PRD_DELETE

Delete current print job

PRD_PAUSE

Pause printing

PRD_CONT

Continue paused print job

PRD_RESTART

Restart print job.

rc (**SPLERR**) - returns

Return code.

NO_ERROR (0)

No errors occurred.

ERROR_NOT_SUPPORTED (50)

This request is not supported by the network.

ERROR_BAD_NETPATH (53)

The network path cannot be located.

NERR_NetNotStarted (2102)

The network program is not started.

NERR_DestNotFound (2152)

The print device cannot be found.

NERR_DestIdle (2158)

This print device is idle and cannot accept control operations.

NERR_DestInvalidOp (2159)

This print device request contains an invalid control function.

NERR_ProcNoRespond (2160)

The queue processor is not responding.

NERR_SpoolerNotLoaded (2161)
The spooler is not running.
NERR_InvalidComputer (2351)
The computer name is invalid.

SplControlDevice - Remarks

A paused print device cannot accept new print jobs.

If PRD_DELETE is attempted when there is no current print job, NERR_DestIdle (2158) is returned.

To control jobs on a remote server requires administrator privilege.

SplControlDevice - Example Code

This sample code demonstrates the result of various actions that can be performed on the print device by this function call. At the command line, a print device name is entered along with an action code.

```
#define INCL_SPL
#define INCL_SPLDOSPRINT
#define INCL_SPLERRORS
#include <os2.h>
#include <stdio.h>          /* for printf function */

INT main (argc, argv)
    INT argc;
    CHAR *argv[];
{
    SPLERR splerr ;
    ULONG  ulControl=0L ;
    PSZ     pszComputerName = NULL ;
    PSZ     pszPrintDeviceName ;

    /* Input a Print Device Name and an Action Code on the command line */
    if (argc != 3)
    {
        printf("Syntax is: qcontrol PrintDeviceName ActionCode \n");
        printf("Action codes are: D-Delete, P-Pause, C-Continue, R-Restart\n\n");
        DosExit( EXIT_PROCESS , 0 ) ;
    }

    /* Get the print device name from the first input parameter. */
    pszPrintDeviceName = argv[1];

    /* Get the action code from the second input parameter. */
    switch (argv[2][0])
    {
        case 'D':
            ulControl = PRD_DELETE ;
            break;
    }
```

```

        case 'P':
            ulControl = PRD_PAUSE ;
            break;
        case 'C':
            ulControl = PRD_CONT ;
            break;
        case 'R':
            ulControl = PRD_RESTART ;
            break;
        default:
            printf("Invalid code\n");
            DosExit( EXIT_PROCESS , 0 ) ;
    }
    /* Call the function with the parameters obtained from the command line. */
    splerr = SplControlDevice(pszComputerName, pszPrintDeviceName, ulControl);

    /* If there is an error returned, print it. */
    if (splerr != 0L)
    {
        switch (splerr)
        {
            case NERR_DestNotFound :
                printf("Destination does not exist.\n");
                break;
            case NERR_DestIdle:
                printf("This print device is idle - can't do control ops. \n");
                break;
            default:
                printf("Errorcode = %ld\n",splerr);
        }
    } else {
        printf("The print job operation was performed.\n\n");
    }

SplCopyJob

SplCopyJob - Syntax

This function copies a job in a print queue.

Currently there is a restriction that a job can only be copied onto the same queue (and computer) as the original job.

```

#define INCL_SPL /* Or use INCL_PM, */
#include <os2.h>

PSZ      pszSrcComputerName; /* Name of computer where job is to be copied from. */
PSZ      pszSrcQueueName;   /* Name of queue where job is to be copied from. */
ULONG    ulSrcJob;          /* Source Job identification number. */
PSZ      pszTrgComputerName; /* Name of computer where job is to be copied to. */
PSZ      pszTrgQueueName;   /* Name of queue where job is to be copied to. */
PULONG   pulTrgJob;         /* Job identification number of new job. */
SPLERR    rc;               /* Return code. */

rc = SplCopyJob(pszSrcComputerName, pszSrcQueueName,
               ulSrcJob, pszTrgComputerName, pszTrgQueueName,
               pulTrgJob);

```

SplCopyJob Parameter - pszSrcComputerName

pszSrcComputerName (**PSZ**) - input
 Name of computer where job is to be copied from.

A NULL string specifies the local workstation.

SplCopyJob Parameter - pszSrcQueueName

pszSrcQueueName (**PSZ**) - input
 Name of queue where job is to be copied from.

SplCopyJob Parameter - ulSrcJob

ulSrcJob (**ULONG**) - input
 Source Job identification number.

SplCopyJob Parameter - pszTrgComputerName

pszTrgComputerName (**PSZ**) - input
 Name of computer where job is to be copied to.

A NULL string specifies the local workstation.

SplCopyJob Parameter - pszTrgQueueName

pszTrgQueueName (PSZ) - input

Name of queue where job is to be copied to.

A NULL string specifies the same queue as the original job.

SplCopyJob Parameter - pulTrgJob

pulTrgJob (PULONG) - output

Job identification number of new job.

SplCopyJob Return Value - rc

rc (SPLERR) - returns

Return code.

NO_ERROR (0)

No errors occurred.

ERROR_ACCESS_DENIED (5)

Access is denied.

ERROR_NOT_SUPPORTED (50)

This request is not supported by the network.

ERROR_INVALID_PARAMETER (87)

An invalid parameter is specified.

NERR_NetNotStarted (2102)

The network program is not started.

NERR_QNotFound (2150)

The printer queue does not exist.

NERR_JobNotFound (2151)

The print job does not exist.

NERR_SpoolerNotLoaded (2161)

The spooler is not running.

NERR_InvalidComputer (2351)

The computer name is invalid.

SplCopyJob - Parameters

pszSrcComputerName (PSZ) - input

Name of computer where job is to be copied from.

A NULL string specifies the local workstation.

pszSrcQueueName (PSZ) - input

Name of queue where job is to be copied from.

ulSrcJob (ULONG) - input

Source Job identification number.

pszTrgComputerName ([PSZ](#)) - input
Name of computer where job is to be copied to.

A NULL string specifies the local workstation.

pszTrgQueueName ([PSZ](#)) - input
Name of queue where job is to be copied to.

A NULL string specifies the same queue as the original job.

pulTrgJob ([PULONG](#)) - output
Job identification number of new job.

rc ([SPLERR](#)) - returns
Return code.

NO_ERROR (0)
No errors occurred.
ERROR_ACCESS_DENIED (5)
Access is denied.
ERROR_NOT_SUPPORTED (50)

SplCreateDevice

SplCreateDevice - Syntax

This function establishes a print device on the local workstation or a remote server.

```

#define INCL_SPL /* Or use INCL_PM, */
#include <os2.h>

PSZ      pszComputerName; /* Name of computer where print device is to be added. */
ULONG    ulLevel;         /* Level of detail provided. */
PVOID     pBuf;           /* Data structure. */

```

```
ULONG      cbBuf;          /* Size, in bytes, of data structure. */
SPLERR     rc;             /* Return code. */

rc = SplCreateDevice(pszComputerName, ulLevel,
                    pBuf, cbBuf);
```

SplCreateDevice Parameter - pszComputerName

pszComputerName ([PSZ](#)) - input
Name of computer where print device is to be added.

A NULL string specifies the local workstation.

SplCreateDevice Parameter - ulLevel

ulLevel ([ULONG](#)) - input
Level of detail provided.

This must be 3.

SplCreateDevice Parameter - pBuf

pBuf ([PVOID](#)) - input
Data structure.

It points to a [PRDINFO3](#) data structure.

SplCreateDevice Parameter - cbBuf

cbBuf ([ULONG](#)) - input
Size, in bytes, of data structure.

SplCreateDevice Return Value - rc

rc ([SPLERR](#)) - returns
Return code.

NO_ERROR (0)
No errors occurred.

ERROR_ACCESS_DENIED (5)
Access is denied.

ERROR_NOT_SUPPORTED (50)
This request is not supported by the network.

ERROR_BAD_NETPATH (53)
The network path cannot be located.

ERROR_INVALID_PARAMETER (87)
An invalid parameter is specified.

ERROR_INVALID_NAME (123)
The computer name is invalid.

ERROR_INVALID_LEVEL (124)
The level parameter is invalid.

NERR_NetNotStarted (2102)
The network program is not started.

NERR_BufTooSmall (2123)
The API return buffer is too small.

NERR_DestExists (2153)
The print device already exists.

NERR_DestNoRoom (2157)
The maximum number of print devices has been reached.

NERR_DestInvalidState (2162)
This operation cannot be performed on the print device.

NERR_SpoolNoMemory (2165)
A spooler memory allocation failure occurred.

NERR_DriverNotFound (2166)
The device driver does not exist.

NERR_BadDev (2341)
The device is already in use as a communications device.

NERR_InvalidComputer (2351)
The computer name is invalid.

SplCreateDevice - Parameters

pszComputerName ([PSZ](#)) - input
Name of computer where print device is to be added.

A NULL string specifies the local workstation.

ulLevel ([ULONG](#)) - input
Level of detail provided.

This must be 3.

pBuf ([PVOID](#)) - input
Data structure.

It points to a [PRDINFO3](#) data structure.

cbBuf ([ULONG](#)) - input
Size, in bytes, of data structure.

rc ([SPLERR](#)) - returns
Return code.

NO_ERROR (0)
No errors occurred.

ERROR_ACCESS_DENIED (5)
Access is denied.

ERROR_NOT_SUPPORTED (50)
This request is not supported by the network.

ERROR_BAD_NETPATH (53)
The network path cannot be located.

ERROR_INVALID_PARAMETER (87)

ERROR_INVALID_LEVEL (124)
The level parameter is invalid.

NERR_NetNotStarted (2102)
The network program is not started.

NERR_BufTooSmall (2123)
The API return buffer is too small.

NERR_DestExists (2153)
The print device already exists.

NERR_DestNoRoom (2157)
The maximum number of print devices has been reached.

NERR_DestInvalidState (2162)
This operation cannot be performed on the print device.

NERR_SpoolNoMemory (2165)
A spooler memory allocation failure occurred.

NERR_DriverNotFound (2166)
The device driver does not exist.

NERR_BadDev (2341)
The device is already in use as a communications device.

NERR_InvalidComputer (2351)
The computer name is invalid.

SplCreateDevice - Remarks

The result of this function is the creation of a new print device definition.

The printer is set up to print on the logical address (port) defined by in [PRDINFO3](#). If is NULL, the print device definition is created but is not connected to any logical address. In this case no printing can occur on that print device or from any print queue connected only to that print device. If a logical address is specified, it must already be defined in the PM_SPOOLER_PORTS section of the initialization file.

Note: To change the connection between a print device and a port, use [SplSetDevice](#).

All device drivers and queues specified with the print device must already be defined to the spooler.

To add a remote print device requires administrator privilege.

SplCreateDevice - Example Code

This sample code creates a [PRDINFO3](#) structure with dummy parameters. This structure is then used to call SplCreateDevice to establish a print device on a local workstation.

```
#define INCL_BASE
```

```

#define INCL_DOSMEMMGR
#define INCL_SPL
#define INCL_SPLDOSPRINT

#include <os2.h>
#include <stdio.h>      /* for printf function */
#include <string.h>     /* for strcpy function */

INT main (argc, argv)
    INT argc;
    CHAR *argv[];
{
    ULONG    splerr    ;
    ULONG    cbBuf;
    ULONG    ulLevel  ;
    PSZ      pszComputerName ;
    PSZ      pszPrintDeviceName ;
    PRDINFO3 prd3    ;

    if (argc != 2)
    {
        printf("Syntax:  sdprt  DeviceName \n");
        DosExit( EXIT_PROCESS , 0 ) ;
    }
    /* We are going to create a print device on the local workstation. */
    pszComputerName = (PSZ)NULL ;

    /* Get the name from the command line. */
    pszPrintDeviceName = argv[1];

    /* Level 3 is valid. We will use level 3. */
    ulLevel = 3;

    /* Get size of buffer needed for a PRDINFO3 structure. */
    cbBuf = sizeof(PRDINFO3);

    /* Set up the structure with dummy parameters. */
    prd3.pszPrinterName = pszPrintDeviceName;
    prd3.pszUserName = NULL;

SplCreatePort

SplCreatePort - Syntax

Description:

This function is called to create a printer port. The printer port can be a virtual port.

Note: There is currently no support for using this API to remotely add a printer port.

```
#define INCL_SPL
#define INCL_SPLBIDI
#include <os2.h>

PSZ      pszComputerName; /* Name of computer where port is to be installed. */
PSZ      pszPortName;     /* Name of printer port to install. */
PSZ      pszPortDriver;   /* Name of the port driver assigned to this port. */
ULONG    ulVersion;       /* Version of port to create. */
PVOID    pBuf;            /* Port-driver-specific buffer. */
ULONG    cbBuf;           /* Length of the data in pBuf, in bytes. */
ULONG    rc;              /* Return codes. */

rc = SplCreatePort(pszComputerName, pszPortName,
                  pszPortDriver, ulVersion, pBuf, cbBuf);
```

SplCreatePort Parameter - pszComputerName

pszComputerName ([PSZ](#)) - input

Name of computer where port is to be installed.

A NULL string is used for installing a port on the local machine. This parameter currently must be NULL.

SplCreatePort Parameter - pszPortName

pszPortName ([PSZ](#)) - input

Name of printer port to install.

This port, virtual or regular, must not already exist. Following is an example of a port name:
LPT5

SplCreatePort Parameter - pszPortDriver

pszPortDriver ([PSZ](#)) - input

Name of the port driver assigned to this port.

If not NULL, this field must specify an installed port driver; it is case-sensitive. Following is an example of a port driver:
PARALLEL

SplCreatePort Parameter - ulVersion

ulVersion ([ULONG](#)) - input

Version of port to create.

Values are as follows:

SPLPORT_VERSION_REGULAR - 0

Creates normal printer port that can be connected to a print queue. This port will remain after a reboot.

SPLPORT_VERSION_VIRTUAL - 1

Creates a virtual printer port that can only be used for querying and setting. This port exists only until the spooler is disabled or the machine is rebooted.

SplCreatePort Parameter - pBuf

pBuf ([PVOID](#)) - input

Port-driver-specific buffer.

If SPLPORT_VERSION_VIRTUAL is set, this is a port-driver-specific buffer that contains information necessary for the port driver to set up a virtual connection to the printer. There cannot be any imbedded pointers in this buffer. This buffer will be passed to the port driver with the BIDI_ADD_VIRTUAL_PORT command.

SplCreatePort Parameter - cbBuf

cbBuf ([ULONG](#)) - input

Length of the data in *pBuf*, in bytes.

SplCreatePort Return Value - rc

rc (**ULONG**) - returns
Return codes.

0	Success
ERROR_DEVICE_IN_USE(99)	Port name is already defined.
ERROR_FILE_NOT_FOUND(2)	Port driver name is not valid.
ERROR_INVALID_LEVEL(124)	<i>ulVersion</i> is not 0 or 1.
ERROR_INVALID_PARAMETER(87)	An invalid buffer was given.
ERROR_NOT_ENOUGH_MEMORY(8)	Not enough memory to satisfy request.
ERROR_NOT_SUPPORTED(50)	<i>pszComputerName</i> is not supported, or the port driver does not support the virtual port.
PMERR_SPL_SPOOLER_NOT_INSTALLED(0x4009)	Spooler not enabled; virtual ports require spooler to be enabled.

SplCreatePort - Parameters

pszComputerName (**PSZ**) - input
Name of computer where port is to be installed.

A NULL string is used for installing a port on the local machine. This parameter currently must be NULL.

pszPortName (**PSZ**) - input
Name of printer port to install.

This port, virtual or regular, must not already exist. Following is an example of a port name:
LPT5

pszPortDriver (**PSZ**) - input
Name of the port driver assigned to this port.

If not NULL, this field must specify an installed port driver; it is case-sensitive. Following is an example of a port driver:
PARALLEL

ulVersion (**ULONG**) - input
Version of port to create.

Values are as follows:

SPLPORT_VERSION_REGULAR - 0
Creates normal printer port that can be connected to a print queue. This port will remain after a reboot.

SPLPORT_VERSION_VIRTUAL - 1
Creates a virtual printer port that can only be used for querying and setting. This port exists only until the spooler is disabled or the machine is rebooted.

pBuf (**PVOID**) - input

Port-driver-specific buffer.

If SPLPORT_VERSION_VIRTUAL is set, this is a port-driver-specific buffer that contains information necessary for the port driver to set up a virtual connection to the printer. There cannot be any imbedded pointers in this buffer. This buffer will be passed to the port driver with the BIDI_ADD_VIRTUAL_PORT command.

cbBuf ([ULONG](#)) - input
Length of the data in *pBuf*, in bytes.

rc ([ULONG](#)) - returns
Return codes.

0	Success
ERROR_DEVICE_IN_USE(99)	Port name is already defined.
ERROR_FILE_NOT_FOUND(2)	Port driver name is not valid.
ERROR_INVALID_LEVEL(124)	<i>ulVersion</i> is not 0 or 1.
ERROR_INVALID_PARAMETER(87)	An invalid buffer was given.
ERROR_NOT_ENOUGH_MEMORY(8)	Not enough memory to satisfy request.
ERROR_NOT_SUPPORTED(50)	<i>pszComputerName</i> is not supported, or the port driver does not support the virtual port.

SplCreateQueue

SplCreateQueue - Syntax

This function creates a new print queue on the local workstation or on a remote server. A remote server setup requires the LAN Requester and Server software.

```
#define INCL_SPL /* Or use INCL_PM, */
#include <os2.h>

PSZ      pszComputerName; /* Name of computer where queue is to be created. */
ULONG    ulLevel;         /* Level of detail provided. */
PVOID     pbBuf;          /* Data structure. */
ULONG     cbBuf;          /* Size, in bytes, of data structure. */
SPLERR    rc;             /* Return code. */

rc = SplCreateQueue(pszComputerName, ulLevel,
                   pbBuf, cbBuf);
```

SplCreateQueue Parameter - pszComputerName

pszComputerName (**PSZ**) - input
Name of computer where queue is to be created.

A NULL string specifies a local workstation.

SplCreateQueue Parameter - ulLevel

ulLevel (**ULONG**) - input
Level of detail provided.

This must be 3 or 6.

SplCreateQueue Parameter - pbBuf

pbBuf (**PVOID**) - input
Data structure.

It points to a data structure depending on the value specified in *ulLevel* as follows:

	<i>ulLevel</i>	Buffer Content.
3		a PRQINFO3 data structure
6		a PRQINFO6 data structure

SplCreateQueue Parameter - cbBuf

cbBuf ([ULONG](#)) - input
Size, in bytes, of data structure.

It must be greater than 0.

SplCreateQueue Return Value - rc

rc ([SPLERR](#)) - returns
Return code.

NO_ERROR (0)
No errors occurred.

ERROR_NOT_SUPPORTED (50)
This request is not supported by the network.

ERROR_INVALID_PARAMETER (87)
An invalid parameter is specified.

ERROR_INVALID_NAME (123)
The computer name is invalid.

ERROR_INVALID_LEVEL (124)
The level parameter is invalid.

NERR_NetNotStarted (2102)
The network program is not started.

NERR_RedirectedPath (2117)
The operation is invalid on a redirected resource.

NERR_BufTooSmall (2123)
The API return buffer is too small.

NERR_DestNotFound (2152)
The printer destination cannot be found.

NERR_QExists (2154)
The printer queue already exists.

NERR_DestInvalidState (2162)
This operation cannot be performed on the print destination in its current state.

NERR_SpoolNoMemory (2165)
A spooler memory allocation failure occurred.

NERR_DriverNotFound (2166)
The device driver does not exist.

NERR_DataTypeInvalid (2167)
The data type is not supported by the queue processor.

NERR_ProcNotFound (2168)
The queue processor is not installed.

NERR_BadDev (2341)
The requested device is invalid.

NERR_CommDevInUse (2343)
This device is already in use as a communications device.

NERR_InvalidComputer (2351)
The computer name is invalid.

SplCreateQueue - Parameters

pszComputerName ([PSZ](#)) - input
Name of computer where queue is to be created.

A NULL string specifies a local workstation.

ulLevel ([ULONG](#)) - input

Level of detail provided.

This must be 3 or 6.

pbBuf ([PVOID](#)) - input
Data structure.

It points to a data structure depending on the value specified in *uLevel* as follows:

	<i>uLevel</i>	Buffer Content.
3		a PRQINFO3 data structure
6		a PRQINFO6 data structure

cbBuf ([ULONG](#)) - input
Size, in bytes, of data structure.

It must be greater than 0.

rc ([SPLERR](#)) - returns
Return code.

NO_ERROR (0)	No errors occurred.
ERROR_NOT_SUPPORTED (50)	This request is not supported by the network.
ERROR_INVALID_PARAMETER (87)	An invalid parameter is specified.
ERROR_INVALID_NAME (123)	The computer name is invalid.
ERROR_INVALID_LEVEL (124)	The level parameter is invalid.
NERR_NetNotStarted (2102)	The network program is not started.
NERR_RedirectedPath (2117)	The operation is invalid on a redirected resource.
NERR_BufTooSmall (2123)	The API return buffer is too small.
NERR_DestNotFound (2152)	The printer destination cannot be found.
NERR_QExists (2154)	The printer queue already exists.
NERR_DestInvalidState (2162)	This operation cannot be performed on the print destination in its current state.
NERR_SpoolNoMemory (2165)	A spooler memory allocation failure occurred.
NERR_DriverNotFound (2166)	The device driver does not exist.
NERR_DataTypeInvalid (2167)	The data type is not supported by the queue processor.
NERR_ProcNotFound (2168)	The queue processor is not installed.
NERR_BadDev (2341)	The requested device is invalid.
NERR_CommDevInUse (2343)	This device is already in use as a communications device.
NERR_InvalidComputer (2351)	The computer name is invalid.

SplCreateQueue - Remarks

To create a queue on a remote server requires administrator privilege. The following fields are required in [PRQINFO3](#) or [PRQINFO6](#):

- *uPriority*
- *uStartTime*
- *uUntilTime*
- *pszSepFile*

- *pszParams*

If a queue of the name specified in *pszName* already exists on *pszComputerName*, the call fails unless the queue is marked for deletion. In this case, the queue is not deleted, and the creation fields are used to perform a [SplSetQueue](#) function on the queue.

If *pszPrinters* is NULL, the queue is created but not connected to any printer.

pszDriverName can be a NULL string, in which case *pDriverData* is ignored. Otherwise, *pszDriverName* must refer to the name of a device driver that is already defined in the initialization file (for example, "IBM4019").

SplCreateQueue - Example Code

This sample code creates a queue on the local workstation. The queue is created with dummy parameters. The name is entered at the command line.

```
#define INCL_BASE
#define INCL_SPL
#define INCL_SPLDOSPRINT

#include <os2.h>
#include <stdio.h>
#include <string.h>

INT main (argc, argv )
{
    INT argc;
    CHAR *argv[];

    ULONG splerr ;
    ULONG cbBuf;
    ULONG ulLevel ;
    PSZ pszComputerName ;
    PSZ pszQueueName ;
    PRQINFO3 prq3 ;

    if (argc != 2)
    {
        printf("Syntax:  sqcrt QueueName \n");
        DosExit( EXIT_PROCESS , 0 ) ;
    }

    pszComputerName = (PSZ)NULL ;
    ulLevel = 3L;

    /* Get the queue name from the argument entered at */
    /* the command line. */
    pszQueueName = argv[1];

    /* Determine the size of the needed buffer. */
    cbBuf = sizeof(PRQINFO3);

    /* Set up the structure with some dummy parameters. */
    prq3.pszName = pszQueueName;
    prq3.uPriority=5;
    prq3.uStartTime=0;
```

```

prq3.uUntilTime=0;
prq3.pszSepFile="c:\\os2\\sample.sep";
prq3.pszParms=NULL;
prq3.pszPrinters=NULL;
prq3.pszDriverName=NULL;
prq3.pDriverData="IBMNULL";      /* Set to Driver.Device name */

/* Make the call with the proper parameters. */
splerr = SplCreateQueue(pszComputerName, ulLevel,
                        &prq3, cbBuf);

/* Print out the error return code and some other information. */
printf("SplCreateQueue Error=%ld, cbNeeded=%ld\n",
       splerr, cbBuf) ;

DosExit( EXIT_PROCESS , 0 ) ;

SplDeleteDevice

SplDeleteDevice - Syntax

This function deletes a print device.

```

#define INCL_SPL /* Or use INCL_PM, */
#include <os2.h>

PSZ      pszComputerName;    /* Name of computer where print device is. to be deleted. */
PSZ      pszPrintDeviceName; /* Name of Print Device. */
SPLERR   rc;                 /* Return code. */

rc = SplDeleteDevice(pszComputerName, pszPrintDeviceName);

```

SplDeleteDevice Parameter - pszComputerName

pszComputerName (PSZ) - input
Name of computer where print device is. to be deleted.

A NULL string specifies the local workstation.

SplDeleteDevice Parameter - pszPrintDeviceName

pszPrintDeviceName (PSZ) - input
Name of Print Device.

SplDeleteDevice Return Value - rc

rc (SPLERR) - returns
Return code.

NO_ERROR (0)	No errors occurred.
ERROR_ACCESS_DENIED (5)	Access is denied.
ERROR_NOT_SUPPORTED (50)	This request is not supported by the network.
ERROR_BAD_NETPATH (53)	The network path cannot be located.
NERR_NetNotStarted (2102)	The network program is not started.
NERR_DestNotFound (2152)	The print device cannot be found.
NERR_DestInvalidState (2162)	This operation cannot be performed on the print device.
NERR_InvalidComputer (2351)	The computer name is invalid.

SplDeleteDevice - Parameters

pszComputerName (PSZ) - input
Name of computer where print device is. to be deleted.

A NULL string specifies the local workstation.

pszPrintDeviceName (PSZ) - input
Name of Print Device.

rc (SPLERR) - returns
Return code.

NO_ERROR (0)	No errors occurred.
ERROR_ACCESS_DENIED (5)	Access is denied.

ERROR_NOT_SUPPORTED (50)
This request is not supported by the network.
ERROR_BAD_NETPATH (53)
The network path cannot be located.
NERR_NetNotStarted (2102)
The network program is not started.
NERR_DestNotFound (2152)
The print device cannot be found.
NERR_DestInvalidState (2162)
This operation cannot be performed on the print device.
NERR_InvalidComputer (2351)
The computer name is invalid.

SplDeleteDevice - Remarks

If the print device is currently printing a job, SplDeleteDevice fails and returns NERR_DestInvalidState (2162).

To delete a print device on a remote server requires administrator privilege.

SplDeleteJob

SplDeleteJob - Syntax

This function deletes a job from a print queue.

```

#define INCL_SPL /* Or use INCL_PM, */
#include <os2.h>

PSZ      pszComputerName; /* Name of computer where job is to be deleted. */
PSZ      pszQueueName;    /* Queue Name. */
ULONG    ulJob;           /* Job identification number. */
SPLERR    rc;             /* Return code. */

rc = SplDeleteJob(pszComputerName, pszQueueName,
    ulJob);

```

SplDeleteJob Parameter - pszComputerName

pszComputerName (PSZ) - input

Name of computer where job is to be deleted.

A NULL string specifies the local workstation.

SplDeleteJob Parameter - pszQueueName

pszQueueName (PSZ) - input

Queue Name.

SplDeleteJob Parameter - ulJob

ulJob (ULONG) - input

Job identification number.

SplDeleteJob Return Value - rc

rc (SPLERR) - returns

Return code.

NO_ERROR (0)

No errors occurred.

ERROR_ACCESS_DENIED (5)

Access is denied.

ERROR_NOT_SUPPORTED (50)

This request is not supported by the network.

ERROR_BAD_NETPATH (53)

The network path cannot be located.

NERR_NetNotStarted (2102)

The network program is not started.

NERR_JobNotFound (2151)

The print job does not exist.

NERR_ProcNoRespond (2160)

The queue processor is not responding.

NERR_SpoolerNotLoaded (2161)

The spooler is not running.

NERR_InvalidComputer (2351)

The computer name is invalid.

SplDeleteJob - Parameters

pszComputerName ([PSZ](#)) - input

Name of computer where job is to be deleted.

A NULL string specifies the local workstation.

pszQueueName ([PSZ](#)) - input

Queue Name.

ulJob ([ULONG](#)) - input

Job identification number.

rc ([SPLERR](#)) - returns

Return code.

NO_ERROR (0)

No errors occurred.

ERROR_ACCESS_DENIED (5)

Access is denied.

ERROR_NOT_SUPPORTED (50)

This request is not supported by the network.

ERROR_BAD_NETPATH (53)

The network path cannot be located.

NERR_NetNotStarted (2102)

The network program is not started.

NERR_JobNotFound (2151)

The print job does not exist.

NERR_ProcNoRespond (2160)

The queue processor is not responding.

NERR_SpoolerNotLoaded (2161)

The spooler is not running.

NERR_InvalidComputer (2351)

The computer name is invalid.

SplDeleteJob - Remarks

It is possible to delete a job that is currently printing.

If the print queue on which the print job is submitted is pending deletion (following a [SplDeleteQueue](#) call), and the print job is the last in the queue, this function has the additional effect of deleting the queue.

A user with administrator privilege can delete any job.

A job created locally can be deleted locally regardless of user privilege level, but can be deleted remotely only by an administrator.

A remote job can be deleted by a user without administrator privilege only if the username of the person initiating the request is the same as the username of the person who created the job.

SplDeletePort

SplDeletePort - Syntax

Description:

This function is called to remove a printer port.

Note: There is currently no support for using this API to remotely remove a printer port.

```
#define INCL_SPL
#define INCL_SPLBIDI
#include <os2.h>

PSZ      pszComputerName; /* Name of computer where port is to be removed. */
PSZ      pszPortName;    /* Name of printer port to remove. */
ULONG    rc;              /* Return codes. */

rc = SplDeletePort(pszComputerName, pszPortName);
```

SplDeletePort Parameter - pszComputerName

pszComputerName (PSZ) - input

Name of computer where port is to be removed.

A NULL string identifies the local workstation. This currently must be NULL.

SplDeletePort Parameter - pszPortName

pszPortName (PSZ) - input

Name of printer port to remove.

This can be a virtual port name. Following is an example of a port name:
LPT5

Note: This port cannot be removed if it is referenced by a print device.

SplDeletePort Return Value - rc

rc (**ULONG**) - returns
Return codes.

0	Success
ERROR_DEVICE_IN_USE(99)	Port name is connected to a print queue.
ERROR_INVALID_PARAMETER(87)	An invalid buffer was given.
ERROR_NOT_SUPPORTED(50)	<i>pszComputerName</i> is not supported.

SplDeletePort - Parameters

pszComputerName (PSZ) - input
Name of computer where queue is to be deleted.

A NULL string specifies the local workstation.

SplDeleteQueue Parameter - pszQueueName

pszQueueName (PSZ) - input
Queue name.

SplDeleteQueue Return Value - rc

rc (SPLERR) - returns

Return code.

NO_ERROR (0)

No errors occurred.

ERROR_ACCESS_DENIED (5)

Access is denied.

ERROR_NOT_SUPPORTED (50)

This request is not supported by the network.

ERROR_BAD_NETPATH (53)

The network path cannot be located.

ERROR_INVALID_PARAMETER (87)

An invalid parameter is specified.

NERR_NetNotStarted (2102)

The network program is not started.

NERR_QNotFound (2150)

The printer queue does not exist.

NERR_QInvalidState (2163)

This operation cannot be performed on the print queue.

NERR_InvalidComputer (2351)

The computer name is invalid.

SplDeleteQueue - Parameters

pszComputerName (PSZ) - input

Name of computer where queue is to be deleted.

A NULL string specifies the local workstation.

pszQueueName (PSZ) - input

Queue name.

rc (SPLERR) - returns

Return code.

NO_ERROR (0)

No errors occurred.

ERROR_ACCESS_DENIED (5)

Access is denied.

ERROR_NOT_SUPPORTED (50)

This request is not supported by the network.

ERROR_BAD_NETPATH (53)

The network path cannot be located.

ERROR_INVALID_PARAMETER (87)

An invalid parameter is specified.

NERR_NetNotStarted (2102)

The network program is not started.

NERR_QNotFound (2150)

The printer queue does not exist.

NERR_QInvalidState (2163)

This operation cannot be performed on the print queue.

NERR_InvalidComputer (2351)

The computer name is invalid.

SplDeleteQueue - Remarks

If there are print jobs in the queue, SplDeleteQueue marks the queue PRQ3_PENDING. No further jobs can then be added to the queue, which is deleted when all jobs are printed. A queue marked PRQ3_PENDING can be held, and jobs in the queue can be held, restarted, and repeated.

If a queue is held and there are jobs on the queue, a SplDeleteQueue function fails with NERR_QInvalidState (2163).

To delete a queue on a remote server requires administrator privilege on the remote server.

SplDisable

SplDisable - Syntax

Description:

This function is called to disable the OS/2 spooler. The spooler remains disabled across reboots. It can be re-enabled using SplEnable.

Note: There is currently no support for using this API to remotely disable a print spooler.

```
#define INCL_SPL
#define INCL_SPLBIDI
#include <os2.h>

PSZ      pszComputerName; /* Name of the computer on which to disable the spooler. */
PVOID    pReserved;      /* Must be NULL. Reserved for future use. */
ULONG    rc;              /* Return codes. */

rc = SplDisable(pszComputerName, pReserved);
```

SplDisable Parameter - pszComputerName

pszComputerName ([PSZ](#)) - input

Name of the computer on which to disable the spooler.

This value currently must be NULL to disable the local spooler.

SplDisable Parameter - pReserved

pReserved ([PVOID](#)) - input

Must be NULL. Reserved for future use.

SplDisable Return Value - rc

rc ([ULONG](#)) - returns
Return codes.

0	Success
ERROR_INVALID_PARAMETER(87)	An invalid buffer given.
PMERR_SPL_SPOOLER_NOT_INSTALLED(0x4009)	The spooler is not enabled.

SplDisable - Parameters

pszComputerName ([PSZ](#)) - input
Name of the computer on which to disable the spooler.

This value currently must be NULL to disable the local spooler.

pReserved ([PVOID](#)) - input
Must be NULL. Reserved for future use.

rc ([ULONG](#)) - returns
Return codes.

0	Success
ERROR_INVALID_PARAMETER(87)	An invalid buffer given.
PMERR_SPL_SPOOLER_NOT_INSTALLED(0x4009)	The spooler is not enabled.

SplDisplayControlPanel

SplDisplayControlPanel - Syntax

Description:

This function displays a control panel for a printer that is communicating bidirectionally.

```
#define INCL_SPL
#define INCL_SPLBIDI
#include <os2.h>

PSZ      pszComputerName; /* Printer server name for displaying a remote printer panel from a client machine. */
PSZ      pszPortName;    /* Printer port name. */
PSZ      pszDeviceID;    /* Device ID, if known, for the printer connected to pszPortName. */
PSZ      pszControlPanel; /* Name of control panel to call to display the front panel for this printer. */
HAB      hab;            /* Anchor block handle. */
ULONG    flCapabilities; /* Capabilities requested. */
ULONG    rc;             /* Return codes. */

rc = SplDisplayControlPanel(pszComputerName,
                           pszPortName, pszDeviceID, pszControlPanel,
                           hab, flCapabilities);
```

SplDisplayControlPanel Parameter - pszComputerName

pszComputerName (PSZ) - input

Printer server name for displaying a remote printer panel from a client machine.

This parameter is NULL for printers whose ports exist on the current machine.

SplDisplayControlPanel Parameter - pszPortName

pszPortName (PSZ) - input

Printer port name.

The name of the printer port for *pszComputerName*, used to display a control panel. Following is an example of a port name:
LPT1

Device ID, if known, for the printer connected to *pszPortName*.

Name of control panel to call to display the front panel for this printer.

- The name registered with `SplRegisterControlPanel`
- One of the control panel names returned by `SplGetControlPanelList`

Anchor block handle.

Capabilities requested.

Set if an administrator wants the control panel.

Return codes.

Success

ERROR_INVALID_NAME(123)

pszName is not the name of a control panel DLL.

ERROR_NOT_SUPPORTED(50)

A control panel for this printer is not supported by the called control panel DLL.

SplDisplayControlPanel - Parameters

pszComputerName ([PSZ](#)) - input

Printer server name for displaying a remote printer panel from a client machine.

This parameter is NULL for printers whose ports exist on the current machine.

pszPortName ([PSZ](#)) - input

Printer port name.

The name of the printer port for *pszComputerName*, used to display a control panel. Following is an example of a port name:
LPT1

pszDeviceID ([PSZ](#)) - input

Device ID, if known, for the printer connected to *pszPortName*.

pszControlPanel ([PSZ](#)) - input

Name of control panel to call to display the front panel for this printer.

This name can be one of the following:

- The name registered with [SplRegisterControlPanel](#)
- One of the control panel names returned by [SplGetControlPanelList](#)

hAb ([HAB](#)) - input

Anchor block handle.

flCapabilities ([ULONG](#)) - input

Capabilities requested.

FL_ADMIN - 0x00000001

Set if an administrator wants the control panel.

rc ([ULONG](#)) - returns

Return codes.

0 Success

ERROR_INVALID_NAME(123)

pszName is not the name of a control panel DLL.

ERROR_NOT_SUPPORTED(50)

A control panel for this printer is not supported by the called control panel DLL.

SplDisplayControlPanel - Remarks

None.

SplEnable

SplEnable - Syntax

Description:

This function is called to enable the OS/2 spooler.

Note: There is currently no support for using this API to remotely enable a print spooler.

```
#define INCL_SPL
#define INCL_SPLBIDI
#include <os2.h>

PSZ      pszComputerName; /* Name of the computer on which to enable the spooler. */
PSZ      pszDirectory;    /* Name of the directory containing the spool files. */
PVOID    pReserved;       /* Must be NULL. Reserved for future use. */
ULONG    rc;              /* Return codes. */

rc = SplEnable(pszComputerName, pszDirectory,
               pReserved);
```

SplEnable Parameter - pszComputerName

pszComputerName ([PSZ](#)) - input

Name of the computer on which to enable the spooler.

This value currently must be NULL to enable the local spooler.

SplEnable Parameter - pszDirectory

pszDirectory (PSZ) - input
Name of the directory containing the spool files.

This value must currently be set to NULL to use the spooler directory as defined in the SYSTEM INI file.

SplEnable Parameter - pReserved

pReserved (PVOID) - input
Must be NULL. Reserved for future use.

SplEnable Return Value - rc

rc (ULONG) - returns
Return codes.

0	Success
ERROR_INVALID_PARAMETER(87)	An invalid buffer given.
PMERR_SPL_ALREADY_INITIALIZED(0x4FFD)	The spooler is already enabled.
PMERR_SPL_NO_MEMORY(0x4007)	Not enough memory to enable spooler.

SplEnable - Parameters

pszComputerName (PSZ) - input
Name of the computer on which to enable the spooler.

This value currently must be NULL to enable the local spooler.

pszDirectory (PSZ) - input
Name of the directory containing the spool files.

This value must currently be set to NULL to use the spooler directory as defined in the SYSTEM INI file.

pReserved (PVOID) - input
Must be NULL. Reserved for future use.

rc (ULONG) - returns
Return codes.

0	Success
---	---------

ERROR_INVALID_PARAMETER(87)
An invalid buffer given.

PMERR_SPL_ALREADY_INITIALIZED(0x4FFD)
The spooler is already enabled.

PMERR_SPL_NO_MEMORY(0x4007)
Not enough memory to enable spooler.

SplEnumDevice

SplEnumDevice - Syntax

This function lists print device on a server, optionally supplying status information.

```
#define INCL_SPL /* Or use INCL_PM, */
#include <os2.h>

PSZ      pszComputerName; /* Name of computer where print devices are to. be listed. */
ULONG    ulLevel;         /* Level of detail required. */
PVOID    pBuf;            /* Buffer. */
ULONG    cbBuf;           /* Size, in bytes, of Buffer. */
PULONG   pcReturned;      /* Number of entries returned. */
PULONG   pcTotal;         /* Number of entries available. */
PULONG   pcbNeeded;       /* Size in bytes of available information. */
PVOID    pReserved;       /* Reserved value, must be NULL. */
SPLERR   rc;              /* Return code. */

rc = SplEnumDevice(pszComputerName, ulLevel,
                  pBuf, cbBuf, pcReturned, pcTotal, pcbNeeded,
                  pReserved);
```

SplEnumDevice Parameter - pszComputerName

pszComputerName ([PSZ](#)) - input

Name of computer where print devices are to. be listed.

A NULL string specifies the local workstation.

SplEnumDevice Parameter - ulLevel

ulLevel ([ULONG](#)) - input

Level of detail required.

This must be 0, 2 or 3.

SplEnumDevice Parameter - pBuf

pBuf ([PVOID](#)) - output

Buffer.

The returned contents of the buffer depend on the value indicated in *ulLevel* as follows:

<i>ulLevel</i>	Buffer Contents
0	An array of port names. Each name consists of 9 characters, including a null terminator.
2	An array of print device names of type PSZ .
3	An array of PRDINFO3 structures.

If no job is printing on the print device, bits 2-11 of *fsStatus* in the [PRDINFO3](#) data structure are meaningless.

SplEnumDevice Parameter - cbBuf

cbBuf ([ULONG](#)) - input

Size, in bytes, of Buffer.

It must be greater than 0.

SplEnumDevice Parameter - pcReturned

pcReturned ([PULONG](#)) - output

Number of entries returned.

SplEnumDevice Parameter - pcTotal

pcTotal ([PULONG](#)) - output
Number of entries available.

SplEnumDevice Parameter - pcbNeeded

pcbNeeded ([PULONG](#)) - output
Size in bytes of available information.

A value of 0 specifies that the size is not known.

SplEnumDevice Parameter - pReserved

pReserved ([PVOID](#)) - output
Reserved value, must be NULL.

SplEnumDevice Return Value - rc

rc ([SPLERR](#)) - returns
Return code.

NO_ERROR (0)
No errors occurred.

ERROR_NOT_SUPPORTED (50)
This request is not supported by the network.

ERROR_BAD_NETPATH (53)
The network path cannot be located.

ERROR_INVALID_PARAMETER (87)
An invalid parameter is specified.

ERROR_INVALID_LEVEL (124)
The level parameter is invalid.

ERROR_MORE_DATA (234)
Additional data is available.

NERR_NetNotStarted (2102)
The network program is not started.

NERR_InvalidComputer (2351)
The computer name is invalid.

SplEnumDevice - Parameters

pszComputerName ([PSZ](#)) - input

Name of computer where print devices are to be listed.

A NULL string specifies the local workstation.

ulLevel ([ULONG](#)) - input

Level of detail required.

This must be 0, 2 or 3.

pBuf ([PVOID](#)) - output

Buffer.

The returned contents of the buffer depend on the value indicated in *ulLevel* as follows:

<i>ulLevel</i>	Buffer Contents
0	An array of port names. Each name consists of 9 characters, including a null terminator.
2	An array of print device names of type PSZ .
3	An array of PRDINFO3 structures.

If no job is printing on the print device, bits 2-11 of *fsStatus* in the [PRDINFO3](#) data structure are meaningless.

cbBuf ([ULONG](#)) - input

Size, in bytes, of Buffer.

It must be greater than 0.

pcReturned ([PULONG](#)) - output

Number of entries returned.

pcTotal ([PULONG](#)) - output

Number of entries available.

pcbNeeded ([PULONG](#)) - output

Size in bytes of available information.

A value of 0 specifies that the size is not known.

pReserved ([PVOID](#)) - output

Reserved value, must be NULL.

rc ([SPLERR](#)) - returns

Return code.

NO_ERROR (0)

No errors occurred.

ERROR_NOT_SUPPORTED (50)

This request is not supported by the network.

ERROR_BAD_NETPATH (53)

The network path cannot be located.

ERROR_INVALID_PARAMETER (87)

An invalid parameter is specified.

ERROR_INVALID_LEVEL (124)

The level parameter is invalid.

ERROR_MORE_DATA (234)

Additional data is available.

NERR_NetNotStarted (2102)

The network program is not started.

NERR_InvalidComputer (2351)

The computer name is invalid.

SplEnumDevice - Remarks

If *ulLevel* is set to 0, each port name in *pBuf* is truncated to 8 characters.

SplEnumDriver

SplEnumDriver - Syntax

This function lists printer presentation drivers on the local workstation or on a remote server.

```

#define INCL_SPL /* Or use INCL_PM, */
#include <os2.h>

PSZ      pszComputerName; /* Name of computer where queues are to be listed. */
ULONG    ulLevel;         /* Level of detail. */
PVOID    pBuf;           /* Buffer. */
ULONG    cbBuf;           /* Size, in bytes, of Buffer. */
PULONG   pcReturned;      /* Number of entries returned. */
PULONG   pcTotal;         /* Total number of entries available. */
PULONG   pcbNeeded;       /* Size in bytes of available information. */

```

```

PVOID      pReserved;          /* Reserved value, must be NULL. */
SPLERR     rc;                 /* Return code. */

rc = SplEnumDriver(pszComputerName, ulLevel,
                  pBuf, cbBuf, pcReturned, pcTotal, pcbNeeded,
                  pReserved);

```

SplEnumDriver Parameter - pszComputerName

pszComputerName ([PSZ](#)) - input
 Name of computer where queues are to be listed.

A NULL string specifies the local workstation.

SplEnumDriver Parameter - ulLevel

ulLevel ([ULONG](#)) - input
 Level of detail.

The level of detail required. This must be 0.

SplEnumDriver Parameter - pBuf

pBuf ([PVOID](#)) - output
 Buffer.

The returned contents in the buffer are:

	<i>ulLevel</i>	Buffer Contents
0		An array of PRDRIVINFO structures

SplEnumDriver Parameter - cbBuf

cbBuf ([ULONG](#)) - input
 Size, in bytes, of Buffer.

It must be greater than 0.

SplEnumDriver Parameter - pcReturned

pcReturned ([PULONG](#)) - output
Number of entries returned.

SplEnumDriver Parameter - pcTotal

pcTotal ([PULONG](#)) - output
Total number of entries available.

SplEnumDriver Parameter - pcbNeeded

pcbNeeded ([PULONG](#)) - output
Size in bytes of available information.

A value of 0 specifies that the size is not known.

SplEnumDriver Parameter - pReserved

pReserved ([PVOID](#)) - output
Reserved value, must be NULL.

SplEnumDriver Return Value - rc

rc ([SPLERR](#)) - returns
Return code.

- NO_ERROR** (0)
No errors occurred.
- ERROR_ACCESS_DENIED** (5)
Access is denied.
- ERROR_NOT_SUPPORTED** (50)
This request is not supported by the network.
- ERROR_BAD_NETPATH** (53)
The network path cannot be located.
- ERROR_INVALID_PARAMETER** (87)
An invalid parameter is specified.
- ERROR_INVALID_LEVEL** (124)
The level parameter is invalid.
- ERROR_MORE_DATA** (234)
Additional data is available.
- NERR_NetNotStarted** (2102)
The network program is not started.

NERR_BufTooSmall (2123)
The API return buffer is too small.
NERR_InvalidComputer (2351)
The computer name is invalid.

SplEnumDriver - Parameters

pszComputerName ([PSZ](#)) - input
Name of computer where queues are to be listed.

A NULL string specifies the local workstation.

ulLevel ([ULONG](#)) - input
Level of detail.

The level of detail required. This must be 0.

pBuf ([PVOID](#)) - output
Buffer.

The returned contents in the buffer are:

	<i>ulLevel</i>	Buffer Contents
0		An array of PRDRIVINFO structures

cbBuf ([ULONG](#)) - input
Size, in bytes, of Buffer.

It must be greater than 0.

pcReturned ([PULONG](#)) - output
Number of entries returned.

pcTotal ([PULONG](#)) - output
Total number of entries available.

pcbNeeded ([PULONG](#)) - output
Size in bytes of available information.

A value of 0 specifies that the size is not known.

pReserved ([PVOID](#)) - output
Reserved value, must be NULL.

rc ([SPLERR](#)) - returns
Return code.

NO_ERROR (0)	No errors occurred.
ERROR_ACCESS_DENIED (5)	Access is denied.
ERROR_NOT_SUPPORTED (50)	This request is not supported by the network.
ERROR_BAD_NETPATH (53)	The network path cannot be located.

SplEnumJob

SplEnumJob - Syntax

This function lists the jobs in a print queue, optionally supplying status information on each job.

```

#define INCL_SPL /* Or use INCL_PM, */
#include <os2.h>

PSZ      pszComputerName; /* Name of computer where jobs are to be listed. */
PSZ      pszQueueName;   /* Queue name. */
ULONG    ulLevel;        /* Level of detail required. */
PVOID    pBuf;           /* Buffer. */
ULONG    cbBuf;          /* Size, in bytes, of Buffer. */
PULONG   pcReturned;     /* Number of entries returned. */
PULONG   pcTotal;        /* Number of entries available. */
PULONG   pcbNeeded;      /* Size in bytes of available information. */
PVOID    pReserved;      /* Reserved vaue, must be NULL. */
SPLERR   rc;             /* Return code. */

```

```
rc = SplEnumJob(pszComputerName, pszQueueName,
               ulLevel, pBuf, cbBuf, pcReturned, pcTotal,
               pcbNeeded, pReserved);
```

SplEnumJob Parameter - pszComputerName

pszComputerName ([PSZ](#)) - input
Name of computer where jobs are to be listed.

A NULL string specifies the local workstation.

SplEnumJob Parameter - pszQueueName

pszQueueName ([PSZ](#)) - input
Queue name.

SplEnumJob Parameter - ulLevel

ulLevel ([ULONG](#)) - input
Level of detail required.

This must be 0 or 2.

SplEnumJob Parameter - pBuf

pBuf ([PVOID](#)) - output
Buffer.

The returned contents in the buffer depend on the value specified in *ulLevel* as follows:

<i>ulLevel</i>	Buffer Contents
0	An array containing a <i>uJobId</i> for each of <i>pcReturned</i> jobs.
2	An array containing a PRJINFO2 structure for each of <i>pcReturned</i> jobs.

SplEnumJob Parameter - cbBuf

cbBuf ([ULONG](#)) - input
Size, in bytes, of Buffer.

It must be greater than 0.

SplEnumJob Parameter - pcReturned

pcReturned ([PULONG](#)) - output
Number of entries returned.

SplEnumJob Parameter - pcTotal

pcTotal ([PULONG](#)) - output
Number of entries available.

SplEnumJob Parameter - pcbNeeded

pcbNeeded ([PULONG](#)) - output
Size in bytes of available information.

A value of 0 specifies that the size is not known.

SplEnumJob Parameter - pReserved

pReserved ([PVOID](#)) - output
Reserved vaue, must be NULL.

SplEnumJob Return Value - rc

rc ([SPLERR](#)) - returns
Return code.

NO_ERROR (0)
No errors occurred.
ERROR_NOT_SUPPORTED (50)
This request is not supported by the network.

ERROR_INVALID_PARAMETER (87)
 An invalid parameter is specified.
 ERROR_INVALID_LEVEL (124)
 The level parameter is invalid.
 ERROR_MORE_DATA (234)
 Additional data is available.
 NERR_NetNotStarted (2102)
 The network program is not started.
 NERR_QNotFound (2150)
 The printer queue does not exist.
 NERR_SpoolerNotLoaded (2161)
 The spooler is not running.
 NERR_InvalidComputer (2351)
 The computer name is invalid.

SplEnumJob - Parameters

pszComputerName ([PSZ](#)) - input
 Name of computer where jobs are to be listed.

 A NULL string specifies the local workstation.

pszQueueName ([PSZ](#)) - input
 Queue name.

ulLevel ([ULONG](#)) - input
 Level of detail required.

 This must be 0 or 2.

pBuf ([PVOID](#)) - output
 Buffer.

The returned contents in the buffer depend on the value specified in *ulLevel* as follows:

<i>ulLevel</i>	Buffer Contents
0	An array containing a <i>uJobId</i> for each of <i>pcReturned</i> jobs.
2	An array containing a PRJINFO2 structure for each of <i>pcReturned</i> jobs.

cbBuf ([ULONG](#)) - input
 Size, in bytes, of Buffer.

 It must be greater than 0.

pcReturned ([PULONG](#)) - output
 Number of entries returned.

pcTotal ([PULONG](#)) - output
 Number of entries available.

pcbNeeded ([PULONG](#)) - output
 Size in bytes of available information.

 A value of 0 specifies that the size is not known.

pReserved ([PVOID](#)) - output
 Reserved vaue, must be NULL.

rc ([SPLERR](#)) - returns
 Return code.

NO_ERROR (0)
 No errors occurred.
 ERROR_NOT_SUPPORTED (50)
 This request is not supported by the network.

ERROR_INVALID_PARAMETER (87)
 An invalid parameter is specified.
ERROR_INVALID_LEVEL (124)
 The level parameter is invalid.
ERROR_MORE_DATA (234)
 Additional data is available.
NERR_NetNotStarted (2102)
 The network program is not started.
NERR_QNotFound (2150)
 The printer queue does not exist.
NERR_SpoolerNotLoaded (2161)
 The spooler is not running.
NERR_InvalidComputer (2351)
 The computer name is invalid.

SplEnumPort

SplEnumPort - Syntax

This function lists printer ports on the local workstation or on a remote server.

```
#define INCL_SPL /* Or use INCL_PM, */
#include <os2.h>

PSZ      pszComputerName; /* Name of computer where queues are to be listed. */
ULONG    ulLevel;         /* Level of detail. */
PVOID    pBuf;            /* Buffer. */
ULONG    cbBuf;           /* Size, in bytes, of Buffer. */
PULONG    pcReturned;     /* Number of entries returned. */
PULONG    pcTotal;        /* Total number of entries available. */
PULONG    pcbNeeded;      /* Size in bytes of available information. */
PVOID    pReserved;      /* Reserved. */
SPLERR    rc;             /* Return code. */

rc = SplEnumPort(pszComputerName, ulLevel,
                pBuf, cbBuf, pcReturned, pcTotal, pcbNeeded,
                pReserved);
```

SplEnumPort Parameter - pszComputerName

pszComputerName (**PSZ**) - input
Name of computer where queues are to be listed.

A NULL string specifies the local workstation.

SplEnumPort Parameter - ulLevel

ulLevel (**ULONG**) - input
Level of detail.

The level of detail required. This must be 0 or 1.

SplEnumPort Parameter - pBuf

pBuf (**PVOID**) - output
Buffer.

The returned content in the buffer depends on the value specified in *uLevel* as follows:

	<i>uLevel</i>	Buffer Contents
0		An array of PRPORTINFO structures
1		An array of PRPORTINFO1 structures

SplEnumPort Parameter - cbBuf

cbBuf (**ULONG**) - input
Size, in bytes, of Buffer.

SplEnumPort Parameter - pcReturned

pcReturned (**PULONG**) - output
Number of entries returned.

SplEnumPort Parameter - pcTotal

pcTotal (**PULONG**) - output
Total number of entries available.

SplEnumPort Parameter - pcbNeeded

pcbNeeded (**PULONG**) - output
Size in bytes of available information.

A value of 0 specifies that the size is not known.

SplEnumPort Parameter - pReserved

pReserved ([PVOID](#)) - output
Reserved.

This must be NULL.

SplEnumPort Return Value - rc

rc ([SPLERR](#)) - returns
Return code.

NO_ERROR (0)
No errors occurred.

ERROR_ACCESS_DENIED (5)
Access is denied.

ERROR_NOT_SUPPORTED (50)
This request is not supported by the network.

ERROR_BAD_NETPATH (53)
The network path cannot be located.

ERROR_INVALID_PARAMETER (87)
An invalid parameter is specified.

ERROR_INVALID_LEVEL (124)
The level parameter is invalid.

ERROR_MORE_DATA (234)
Additional data is available.

NERR_NetNotStarted (2102)
The network program is not started.

NERR_BufTooSmall (2123)
The API return buffer is too small.

NERR_InvalidComputer (2351)
The computer name is invalid.

SplEnumPort - Parameters

pszComputerName ([PSZ](#)) - input
Name of computer where queues are to be listed.

A NULL string specifies the local workstation.

ulLevel ([ULONG](#)) - input
Level of detail.

The level of detail required. This must be 0 or 1.

pBuf ([PVOID](#)) - output
Buffer.

The returned content in the buffer depends on the value specified in *ulLevel* as follows:

<i>ulLevel</i>	Buffer Contents
0	An array of PRPORTINFO structures
1	An array of PRPORTINFO1 structures

cbBuf ([ULONG](#)) - input
Size, in bytes, of Buffer.

pcReturned ([PULONG](#)) - output
Number of entries returned.

pcTotal ([PULONG](#)) - output
Total number of entries available.

pcbNeeded ([PULONG](#)) - output
Size in bytes of available information.

A value of 0 specifies that the size is not known.

pReserved ([PVOID](#)) - output
Reserved.

This must be NULL.

rc ([SPLERR](#)) - returns
Return code.

NO_ERROR (0)
No errors occurred.
ERROR_ACCESS_DENIED (5)
Access is denied.
ERROR_NOT_SUPPORTED (50)
This request is not supported by the network.
ERROR_BAD_NETPATH (53)
The network path cannot be located.
ERROR_INVALID_PARAMETER (87)
An invalid parameter is specified.
ERROR_INVALID_LEVEL (124)

                    pcbNeeded, pReserved);
```

SplEnumPrinter Parameter - PSZComputerName

PSZComputerName ([PSZ](#)) - input
Name of computer where queues are to be listed.

This must be NULL.

SplEnumPrinter Parameter - ulLevel

ulLevel ([ULONG](#)) - input
Level of detail required.

This must be 0.

SplEnumPrinter Parameter - flType

flType ([ULONG](#)) - input
Type of print destinations required.

SPL_PR_QUEUE
Return only queues
SPL_PR_DIRECT_DEVICE
Return only direct print devices
SPL_PR_QUEUED_DEVICE
Return only queued print devices
SPL_PR_LOCAL_ONLY
Return only local print destinations

SplEnumPrinter Parameter - pBuf

pBuf ([PVOID](#)) - output
Buffer.

The returned contents in the buffer are as follows:

<i>ulLevel</i>	Buffer Contents
0	An array of PRINTERINFO structures.

When the names of print destinations are returned, calls can be made to [SplQueryQueue](#) or [SplQueryDevice](#) to find out further information about the print destination.

SplEnumPrinter Parameter - cbBuf

cbBuf ([ULONG](#)) - input
Size, in bytes, of Buffer.

It must be greater than 0.

SplEnumPrinter Parameter - pcReturned

pcReturned ([PULONG](#)) - output
Number of entries returned.

SplEnumPrinter Parameter - pcTotal

pcTotal ([PULONG](#)) - output
Number of entries available.

SplEnumPrinter Parameter - pcbNeeded

pcbNeeded ([PULONG](#)) - output
Size in bytes of available information.

A value of 0 specifies that the size is not known.

SplEnumPrinter Parameter - pReserved

pReserved ([PVOID](#)) - output
Reserved value, must be NULL.

SplEnumPrinter Return Value - rc

rc ([SPLERR](#)) - returns
Return code.

- NO_ERROR** (0)
No errors occurred.
- ERROR_NOT_SUPPORTED** (50)
This request is not supported by the network.
- ERROR_INVALID_PARAMETER** (87)
An invalid parameter is specified.

The network program is not started.
- NERR_BufTooSmall** (2123)
The API return buffer is too small.

SplEnumPrinter - Parameters

PSZComputerName ([PSZ](#)) - input
Name of computer where queues are to be listed.

This must be NULL.

ulLevel ([ULONG](#)) - input
Level of detail required.

This must be 0.

flType ([ULONG](#)) - input
Type of print destinations required.

- SPL_PR_QUEUE**
Return only queues
- SPL_PR_DIRECT_DEVICE**
Return only direct print devices
- SPL_PR_QUEUED_DEVICE**
Return only queued print devices
- SPL_PR_LOCAL_ONLY**
Return only local print destinations

pBuf ([PVOID](#)) - output
Buffer.

The returned contents in the buffer are as follows:

<i>ulLevel</i>	Buffer Contents
0	An array of PRINTERINFO structures.

When the names of print destinations are returned, calls can be made to [SplQueryQueue](#) or [SplQueryDevice](#) to find out further information about the print destination.

cbBuf ([ULONG](#)) - input
Size, in bytes, of Buffer.

It must be greater than 0.

pcReturned ([PULONG](#)) - output
Number of entries returned.

pcTotal ([PULONG](#)) - output
Number of entries available.

pcbNeeded ([PULONG](#)) - output
Size in bytes of available information.

A value of 0 specifies that the size is not known.

pReserved ([PVOID](#)) - output
Reserved value, must be NULL.

rc ([SPLERR](#)) - returns
Return code.

NO_ERROR (0)	No errors occurred.
ERROR_NOT_SUPPORTED (50)	This request is not supported by the network.
ERROR_INVALID_PARAMETER (87)	An invalid parameter is specified.
ERROR_INVALID_LEVEL (124)	The level parameter is invalid.
ERROR_MORE_DATA (234)	Additional data is available.

SplEnumQueue

SplEnumQueue - Syntax

This function lists print queues on the local workstation or on a remote server, optionally supplying additional information.

```
#define INCL_SPL /* Or use INCL_PM, */
#include <os2.h>

PSZ      pszComputerName; /* Name of computer where queues are to be listed. */
ULONG    ulLevel;         /* Level of detail. */
PVOID    pBuf;            /* Buffer. */
ULONG    cbBuf;           /* Size, in bytes, of Buffer. */
PULONG    pcReturned;     /* Number of entries returned. */
PULONG    pcTotal;        /* Total number of entries available. */
PULONG    pcbNeeded;      /* Size in bytes of available information. */
PVOID     pReserved;      /* Reserved value, must be NULL. */
SPLERR    rc;             /* Return code. */

rc = SplEnumQueue(pszComputerName, ulLevel,
                  pBuf, cbBuf, pcReturned, pcTotal, pcbNeeded,
                  pReserved);
```

SplEnumQueue Parameter - pszComputerName

pszComputerName ([PSZ](#)) - input

Name of computer where queues are to be listed.

A NULL string specifies the local workstation.

SplEnumQueue Parameter - ulLevel

ulLevel ([ULONG](#)) - input
Level of detail.

The level of detail required. This must be 3, 4, 5, 6 or 7.

SplEnumQueue Parameter - pBuf

pBuf ([PVOID](#)) - output
Buffer.

The returned contents in the buffer depend on the value specified in *ulLevel* as follows:

<i>ulLevel</i>	Buffer Contents
3	An array of PRQINFO3 structures. The <i>IsType</i> bit PRQ3_TYPE_APPDEFAULT is set for the application default queue only.
4	An array of <i>*pcReturned</i> PRQINFO3 structures in which each PRQINFO3 structure is followed by an array of PRJINFO2 structures, one for each job in the queue. <i>cJobs</i> in the PRQINFO3 structure gives the number of jobs in the array.
5	An array of PSZ, each pointing to a queue name.
6	An array of PRQINFO6 structures
7	An array of <i>*pcReturned</i> PRQINFO3 structures in which each PRQINFO3 structure is followed by an array of PRJINFO4 structures, one for each job in the queue. <i>cJobs</i> in the PRQINFO3 structure gives the number of jobs in the array.

SplEnumQueue Parameter - cbBuf

cbBuf ([ULONG](#)) - input
Size, in bytes, of Buffer.

It must be greater than 0. Some systems do not allow a size greater than 65535.

SplEnumQueue Parameter - pcReturned

pcReturned ([PULONG](#)) - output
Number of entries returned.

SplEnumQueue Parameter - pcTotal

pcTotal ([PULONG](#)) - output
Total number of entries available.

SplEnumQueue Parameter - pcbNeeded

pcbNeeded ([PULONG](#)) - output
Size in bytes of available information.

A value of 0 specifies that the size is not known. This can occur when enumerating queues on a print server. To determine the buffer size needed, the caller should allocate a buffer in 4096-byte increments until a successful return code is received, or until the buffer size exceeds 65535.

SplEnumQueue Parameter - pReserved

pReserved ([PVOID](#)) - output
Reserved value, must be NULL.

SplEnumQueue Return Value - rc

rc ([SPLERR](#)) - returns
Return code.

- NO_ERROR (0)
No errors occurred.
- ERROR_ACCESS_DENIED (5)
Access is denied.
- ERROR_NOT_SUPPORTED (50)
This request is not supported by the network.
- ERROR_BAD_NETPATH (53)
The network path cannot be located.
- ERROR_INVALID_PARAMETER (87)
An invalid parameter is specified.
- ERROR_INVALID_LEVEL (124)
The level parameter is invalid.
- ERROR_MORE_DATA (234)
Additional data is available.
- NERR_NetNotStarted (2102)
The network program is not started.
- NERR_BufTooSmall (2123)
The API return buffer is too small.
- NERR_InvalidComputer (2351)
The computer name is invalid.

SplEnumQueue - Parameters

pszComputerName (**PSZ**) - input

Name of computer where queues are to be listed.

A NULL string specifies the local workstation.

ulLevel (**ULONG**) - input

Level of detail.

The level of detail required. This must be 3, 4, 5, 6 or 7.

pBuf (**PVOID**) - output

Buffer.

The returned contents in the buffer depend on the value specified in *ulLevel* as follows:

<i>ulLevel</i>	Buffer Contents
3	An array of PRQINFO3 structures. The <i>IsType</i> bit PRQ3_TYPE_APPDEFAULT is set for the application default queue only.
4	An array of <i>*pcReturned</i> PRQINFO3 structures in which each PRQINFO3 structure is followed by an array of PRJINFO2 structures, one for each job in the queue. <i>cJobs</i> in the PRQINFO3 structure gives the number of jobs in the array.
5	An array of PSZ, each pointing to a queue name.
6	An array of PRQINFO6 structures
7	An array of <i>pcReturned</i> PRQINFO3 structures in which each PRQINFO3 structure is followed by an array of PRJINFO4 structures, one for each job in the queue. <i>cJobs</i> in the PRQINFO3 structure gives the number of jobs in the array.

cbBuf (**ULONG**) - input

Size, in bytes, of Buffer.

It must be greater than 0. Some systems do not allow a size greater than 65535.

pcReturned (**PULONG**) - output

Number of entries returned.

pcTotal (**PULONG**) - output

Total number of entries available.

pcbNeeded (**PULONG**) - output

Size in bytes of available information.

A value of 0 specifies that the size is not known. This can occur when enumerating queues on a print server. To determine the buffer size needed, the caller should allocate a buffer in 4096-byte increments until a successful return code is received, or until the buffer size exceeds 65535.

pReserved (**PVOID**) - output

Reserved value, must be NULL.

rc (**SPLERR**) - returns

Return code.

NO_ERROR (0)

No errors occurred.

ERROR_ACCESS_DENIED (5)

Access is denied.

ERROR_NOT_SUPPORTED (50)

This request is not supported by the network.

ERROR_BAD_NETPATH (53)

The network path cannot be located.

ERROR_INVALID_PARAMETER (87)

An invalid parameter is specified.
 ERROR_INVALID_LEVEL (124)
 The level parameter is invalid.
 ERROR_MORE_DATA (234)
 Additional data is available.
 NERR_NetNotStarted (2102)
 The network program is not started.
 NERR_BufTooSmall (2123)
 The API return buffer is too small.
 NERR_InvalidComputer (2351)
 The computer name is invalid.

SplEnumQueueProcessor

SplEnumQueueProcessor - Syntax

This function lists printer queue processors on the local workstation or on a remote server.

```

#define INCL_SPL /* Or use INCL_PM, */
#include <os2.h>

PSZ      pszComputerName; /* Name of computer where queues are to be listed. */
ULONG    ulLevel;         /* Level of detail. */
PVOID    pBuf;            /* Buffer. */
ULONG    cbBuf;           /* Size, in bytes, of Buffer. */
PULONG   pcReturned;      /* Number of entries returned. */
PULONG   pcTotal;         /* Total number of entries available. */
PULONG   pcbNeeded;       /* Size in bytes of available information. */
PVOID    pReserved;       /* Reserved value, must be NULL. */
SPLERR   rc;              /* Return code. */

rc = SplEnumQueueProcessor(pszComputerName,
                          ulLevel, pBuf, cbBuf, pcReturned, pcTotal,
                          pcbNeeded, pReserved);

```

SplEnumQueueProcessor Parameter - pszComputerName

pszComputerName (**PSZ**) - input
Name of computer where queues are to be listed.

A NULL string specifies the local workstation.

SplEnumQueueProcessor Parameter - ulLevel

ulLevel (**ULONG**) - input
Level of detail.

The level of detail required. This must be 0.

SplEnumQueueProcessor Parameter - pBuf

pBuf (**PVOID**) - output
Buffer.

The returned contents of the buffer are as follows:

	<i>ulLevel</i>	Buffer Contents
0		An array of PRQPROCINFO structures

SplEnumQueueProcessor Parameter - cbBuf

cbBuf (**ULONG**) - input
Size, in bytes, of Buffer.

It must be greater than 0.

SplEnumQueueProcessor Parameter - pcReturned

pcReturned (**PULONG**) - output
Number of entries returned.

SplEnumQueueProcessor Parameter - pcTotal

pcTotal (**PULONG**) - output
Total number of entries available.

SplEnumQueueProcessor Parameter - pcbNeeded

pcbNeeded (**PULONG**) - output
Size in bytes of available information.

A value of 0 specifies that the size is not known.

SplEnumQueueProcessor Parameter - pReserved

pReserved (**PVOID**) - output
Reserved value, must be NULL.

SplEnumQueueProcessor Return Value - rc

rc (**SPLERR**) - returns
Return code.

NO_ERROR (0)	No errors occurred.
ERROR_ACCESS_DENIED (5)	Access is denied.
ERROR_NOT_SUPPORTED (50)	This request is not supported by the network.
ERROR_BAD_NETPATH (53)	The network path cannot be located.
ERROR_INVALID_PARAMETER (87)	An invalid parameter is specified.
ERROR_INVALID_LEVEL (124)	The level parameter is invalid.
ERROR_MORE_DATA (234)	Additional data is available.
NERR_NetNotStarted (2102)	The network program is not started.
NERR_BufTooSmall (2123)	The API return buffer is too small.
NERR_InvalidComputer (2351)	The computer name is invalid.

SplEnumQueueProcessor - Parameters

pszComputerName (**PSZ**) - input
Name of computer where queues are to be listed.

A NULL string specifies the local workstation.

ulLevel (**ULONG**) - input
Level of detail.

The level of detail required. This must be 0.

pBuf (**PVOID**) - output
Buffer.

The returned contents of the buffer are as follows:

<i>ulLevel</i>	Buffer Contents
0	An array of PRQPROCINFO structures

cbBuf (**ULONG**) - input
Size, in bytes, of Buffer.

It must be greater than 0.

pcReturned (**PULONG**) - output
Number of entries returned.

pcTotal (**PULONG**) - output
Total number of entries available.

pcbNeeded (**PULONG**) - output
Size in bytes of available information.

A value of 0 specifies that the size is not known.

pReserved (**PVOID**) - output
Reserved value, must be NULL.

rc (**SPLERR**) - returns
Return code.

NO_ERROR (0)	No errors occurred.
ERROR_ACCESS_DENIED (5)	Access is denied.
ERROR_NOT_SUPPORTED (50)	This request is not supported by the network.
ERROR_BAD_NETPATH (53)	The network path cannot be located.
ERROR_INVALID_PARAMETER (87)	An invalid parameter is specified.
ERROR_INVALID_LEVEL (124)	The level parameter is invalid.
ERROR_MORE_DATA (234)	Additional data is available.
NERR_NetNotStarted (2102)	The network program is not started.
NERR_BufTooSmall (2123)	The API return buffer is too small.
NERR_InvalidComputer (2351)	The computer name is invalid.

SplGetControlPanelList

SplGetControlPanelList - Syntax

Description:

This function queries installed control panel DLLs for support for the printer attached to the given port.

```

#define INCL_SPL
#define INCL_SPLBIDI
#include <os2.h>

PSZ      pszComputerName; /* Name of computer connected to the printer port. */
PSZ      pszPortName;    /* Name of printer port on pszComputerName used to determine if a control panel ca
PSZ      pszDeviceID;    /* Device ID, if known, for the printer connected to pszPortName. */
ULONG    flCapabilities; /* Compatibilities requested. */
PSZ      pszListOfPanels; /* Receives comma-separated list of control panel names capable of displaying a co
ULONG    cbBuf;          /* Length of buffer, in bytes, pointed to by pszListOfPanels. */
PULONG   pcbNeeded;      /* Receives length, in bytes, of buffer needed to store entire list of control pan
ULONG    rc;              /* Return codes. */

rc = SplGetControlPanelList(pszComputerName,
    pszPortName, pszDeviceID, flCapabilities,
    pszListOfPanels, cbBuf, pcbNeeded);

```

SplGetControlPanelList Parameter - pszComputerName

pszComputerName (PSZ) - input
Name of computer connected to the printer port.

This is NULL for printers whose port exists on the current machine.

SplGetControlPanelList Parameter - pszPortName

pszPortName (PSZ) - input
Name of printer port on *pszComputerName* used to determine if a control panel can be displayed.

SplGetControlPanelList Parameter - pszDeviceID

pszDeviceID (PSZ) - input
Device ID, if known, for the printer connected to *pszPortName*.

SplGetControlPanelList Parameter - flCapabilities

flCapabilities (ULONG) - input
Compatibilities requested.

FL_ADMIN - 0x00000001 Set if an administrator wants the control panel.

SplGetControlPanelList Parameter - pszListOfPanels

pszListOfPanels (PSZ) - output
Receives comma-separated list of control panel names capable of displaying a control panel for the printer.

SplGetControlPanelList Parameter - cbBuf

cbBuf (ULONG) - input
Length of buffer, in bytes, pointed to by *pszListOfPanels*.

SplGetControlPanelList Parameter - pcbNeeded

pcbNeeded (**PULONG**) - output

Receives length, in bytes, of buffer needed to store entire list of control panels for the printer.

SplGetControlPanelList Return Value - rc

rc (**ULONG**) - returns

Return codes.

0 Success

ERROR_NOT_SUPPORTED(50)

A control panel for this printer is not supported by any control panel DLL.

NERR_BufTooSmall(2123)

Need to call again with a bigger buffer.

SplGetControlPanelList - Parameters

pszComputerName (**PSZ**) - input

Name of computer connected to the printer port.

This is NULL for printers whose port exists on the current machine.

pszPortName (**PSZ**) - input

Name of printer port on *pszComputerName* used to determine if a control panel can be displayed.

pszDeviceID (**PSZ**) - input

Device ID, if known, for the printer connected to *pszPortName*.

flCapabilities (**ULONG**) - input

Compatibilities requested.

FL_ADMIN - 0x00000001

Set if an administrator wants the control panel.

pszListOfPanels (**PSZ**) - output

Receives comma-separated list of control panel names capable of displaying a control panel for the printer.

cbBuf (**ULONG**) - input

Length of buffer, in bytes, pointed to by *pszListOfPanels*.

pcbNeeded (**PULONG**) - output

Receives length, in bytes, of buffer needed to store entire list of control panels for the printer.

rc (**ULONG**) - returns

Return codes.

0	Success
ERROR_NOT_SUPPORTED(50)	A control panel for this printer is not supported by any control panel DLL.
NERR_BufTooSmall(2123)	Need to call again with a bigger buffer.

SplGetControlPanelList - Remarks

This function will return Success only for printers that are configured to communicate bidirectionally.

SplGetPortFromQ

SplGetPortFromQ - Syntax

Description:

This function gets a list of ports connected to the print queue for the print object or applications. This function is used by the print object to determine if some menu items can be enabled based on the type of printer port connected to a print queue.

```
#define INCL_SPL
#define INCL_SPLBIDI
#include <os2.h>

PSZ      pszComputerName; /* Name of the computer on which pszQueueName exists. */
PSZ      pszQueueName;   /* Name of print queue. */
ULONG    ulLevel;        /* Level of information to return. */
PVOID    pBuf;           /* Receives the GETPORTFROMQ data structure. */
ULONG    cbBuf;          /* Length of buffer pointed to by pBuf, in bytes. */
ULONG    pcbNeeded;       /* Receives length, in bytes, of buffer needed to return all port data. */
ULONG    rc;              /* Return codes. */

rc = SplGetPortFromQ(pszComputerName, pszQueueName,
                    ulLevel, pBuf, cbBuf, pcbNeeded);
```

SplGetPortFromQ Parameter - pszComputerName

pszComputerName (**PSZ**) - input

Name of the computer on which *pszQueueName* exists.

This value is NULL if the queue is local or if the queue references a network print queue.

SplGetPortFromQ Parameter - pszQueueName

pszQueueName (**PSZ**) - input

Name of print queue.

This is the print queue name on *pszComputerName* or a local print queue name that may reference a network print queue.

SplGetPortFromQ Parameter - ulLevel

ulLevel (**ULONG**) - input

Level of information to return.

Only level 1 is supported, which returns the GETPORTFROMQ data structure.

SplGetPortFromQ Parameter - pBuf

pBuf (**PVOID**) - output

Receives the GETPORTFROMQ data structure.

SplGetPortFromQ Parameter - cbBuf

cbBuf (**ULONG**) - input

Length of buffer pointed to by *pBuf*, in bytes.

SplGetPortFromQ Parameter - pcbNeeded

pcbNeeded (ULONG) - output
Receives length, in bytes, of buffer needed to return all port data.

SplGetPortFromQ Return Value - rc

rc (ULONG) - returns
Return codes.

0	Success
ERROR_BAD_NET_NAME(67)	The computer name cannot be found.
ERROR_BAD_NETPATH(53)	The computer name specified is not available or is invalid.
ERROR_INVALID_LEVEL(124)	<i>ulLevel</i> is not 1.
ERROR_INVALID_PARAMETER(87)	An invalid parameter was specified; most likely an invalid <i>pBuf</i> value.
ERROR_MORE_DATA(234)	Not all data could fit in <i>pBuf</i> .
ERROR_NOT_SUPPORTED(50)	Command not supported on <i>pszComputerName</i> .
NERR_BufTooSmall(2123)	No data could fit in <i>pBuf</i> .
NERR_QNotFound(2150)	The queue name does not exist.

SplGetPortFromQ - Parameters

pszComputerName (PSZ) - input
Name of the computer on which *pszQueueName* exists.

This value is NULL if the queue is local or if the queue references a network print queue.

pszQueueName (PSZ) - input
Name of print queue.

This is the print queue name on *pszComputerName* or a local print queue name that may reference a network print queue.

ulLevel (ULONG) - input
Level of information to return.

Only level 1 is supported, which returns the GETPORTFROMQ data structure.

pBuf (PVOID) - output
Receives the GETPORTFROMQ data structure.

cbBuf ([ULONG](#)) - input
Length of buffer pointed to by *pBuf*, in bytes.

pcbNeeded ([ULONG](#)) - output
Receives length, in bytes, of buffer needed to return all port data.

rc ([ULONG](#)) - returns
Return codes.

0	Success
ERROR_BAD_NET_NAME(67)	The computer name cannot be found.
ERROR_BAD_NETPATH(53)	The computer name specified is not available or is invalid.
ERROR_INVALID_LEVEL(124)	<i>ulLevel</i> is not 1.

SplHoldJob

SplHoldJob - Syntax

This function holds a job in a print queue.

```
#define INCL_SPL /* Or use INCL_PM, */
#include <os2.h>

PSZ      pszComputerName; /* Name of computer where job is to be paused. */
PSZ      pszQueueName;    /* Queue Name. */
ULONG    ulJob;           /* Job identification number. */
SPLERR   rc;              /* Return code. */

rc = SplHoldJob(pszComputerName, pszQueueName,
               ulJob);
```

SplHoldJob Parameter - pszComputerName

pszComputerName (**PSZ**) - input
Name of computer where job is to be paused.

A NULL string specifies the local workstation.

SplHoldJob Parameter - pszQueueName

pszQueueName (**PSZ**) - input
Queue Name.

SplHoldJob Parameter - ulJob

ulJob (**ULONG**) - input
Job identification number.

SplHoldJob Return Value - rc

rc (**SPLERR**) - returns
Return code.

NO_ERROR (0)
No errors occurred.

ERROR_ACCESS_DENIED (5)
Access is denied.
ERROR_NOT_SUPPORTED (50)
This request is not supported by the network.
ERROR_BAD_NETPATH (53)
The network path cannot be located.
NERR_NetNotStarted (2102)
The network program is not installed.
NERR_JobNotFound (2151)
The print job does not exist.
NERR_SpoolerNotLoaded (2161)
The spooler is not running.
NERR_JobInvalidState (2164)
This operation cannot be performed on the print job in its current state.
NERR_InvalidComputer (2351)
The computer name is invalid.

SplHoldJob - Parameters

pszComputerName ([PSZ](#)) - input
Name of computer where job is to be paused.

A NULL string specifies the local workstation.

pszQueueName ([PSZ](#)) - input
Queue Name.

ulJob ([ULONG](#)) - input
Job identification number.

rc ([SPLERR](#)) - returns
Return code.

NO_ERROR (0)
No errors occurred.
ERROR_ACCESS_DENIED (5)
Access is denied.
ERROR_NOT_SUPPORTED (50)
This request is not supported by the network.
ERROR_BAD_NETPATH (53)
The network path cannot be located.
NERR_NetNotStarted (2102)
The network program is not installed.
NERR_JobNotFound (2151)
The print job does not exist.
NERR_SpoolerNotLoaded (2161)
The spooler is not running.
NERR_JobInvalidState (2164)
This operation cannot be performed on the print job in its current state.
NERR_InvalidComputer (2351)
The computer name is invalid.

SplHoldJob - Remarks

If the job is already printing when the call is made, NERR_JobInvalidState (2164) is returned.

A user with administrator privilege can hold any job.

A job created locally can be held locally regardless of user privilege level, but can be held remotely only by an administrator.

A remote job can be held by a user without administrator privilege only if the username of the person initiating the request is the same as the username of the person who created the job.

SplHoldQueue

SplHoldQueue - Syntax

This function holds a print queue.

```
#define INCL_SPL /* Or use INCL_PM, */
#include <os2.h>

PSZ      pszComputerName; /* Name of computer where queue is to be paused. */
PSZ      pszQueueName;   /* Queue name. */
SPLERR   rc;             /* Return code. */

rc = SplHoldQueue(pszComputerName, pszQueueName);
```

SplHoldQueue Parameter - pszComputerName

pszComputerName ([PSZ](#)) - input

Name of computer where queue is to be paused.

A NULL string specifies the local workstation.

SplHoldQueue Parameter - pszQueueName

pszQueueName ([PSZ](#)) - input

Queue name.

SplHoldQueue Return Value - rc

rc ([SPLERR](#)) - returns
Return code.

NO_ERROR (0)	No errors occurred.
ERROR_ACCESS_DENIED (5)	Access is denied.
ERROR_NOT_SUPPORTED (50)	This request is not supported by the network.
ERROR_BAD_NETPATH (53)	The network path cannot be located.
ERROR_INVALID_PARAMETER (87)	An invalid parameter is specified.
NERR_NetNotStarted (2102)	The network program is not started.
NERR_QNotFound (2150)	The printer queue does not exist.
NERR_InvalidComputer (2351)	The computer name is invalid.

SplHoldQueue - Parameters

pszComputerName ([PSZ](#)) - input
Name of computer where queue is to be paused.

A NULL string specifies the local workstation.

pszQueueName ([PSZ](#)) - input
Queue name.

rc ([SPLERR](#)) - returns
Return code.

NO_ERROR (0)	No errors occurred.
ERROR_ACCESS_DENIED (5)	Access is denied.
ERROR_NOT_SUPPORTED (50)	This request is not supported by the network.
ERROR_BAD_NETPATH (53)	The network path cannot be located.
ERROR_INVALID_PARAMETER (87)	An invalid parameter is specified.
NERR_NetNotStarted (2102)	The network program is not started.
NERR_QNotFound (2150)	The printer queue does not exist.
NERR_InvalidComputer (2351)	The computer name is invalid.

SplHoldQueue - Remarks

This function suspends processing of all print jobs except for a job currently printing. Print jobs can be submitted to a held queue, but no jobs will be spooled to a print destination or print processor until the queue is released by a SplHoldQueue call.

To hold a remote queue requires administrator privilege on the remote server.

SplMessageBox

SplMessageBox - Syntax

Description:

SplMessageBox creates and displays a message box.

The message queue will be created (and destroyed) if necessary. In OS/2 2.1, this API may return Retry automatically if the PM message box is displayed for more than three minutes.

```
#include <os2.h>

PSZ      pszAddress; /* Pointer to a string containing the logical address of the device, such as LPT1. */
ULONG    flErrorInfo; /* Error information. */
ULONG    flErrorData; /* Length of the data in bytes. */
PSZ      pszText; /* Pointer to the text string for the message box. */
PSZ      pszCaption; /* Pointer to a string containing a meaningful title for the message box. */
ULONG    idWindow; /* Window ID of the message box window. */
ULONG    fsStyle; /* Bit array specifying the contents and function of the message box. */
ULONG    Response; /* Return codes. */

Response = SplMessageBox(pszAddress, flErrorInfo,
                        flErrorData, pszText, pszCaption,
                        idWindow, fsStyle);
```

SplMessageBox Parameter - pszAddress

pszAddress ([PSZ](#)) - input

Pointer to a string containing the logical address of the device, such as LPT1.

SplMessageBox Parameter - flErrorInfo

flErrorInfo ([ULONG](#)) - input

Error information.

One of the following flags must be set to identify where the error occurred:

SPLINFO_QPERROR	Spooler queue processor error
SPLINFO_DDERROR	Presentation driver error
SPLINFO_SPLERROR	Spooler error
SPLINFO_OTHERERROR	Any other error

One of the following flags is also set to indicate the severity of the error:

SPLINFO_INFORMATION	Information only, no error.
SPLINFO_WARNING	Warning.
SPLINFO_ERROR	Recoverable error.
SPLINFO_SEVERE	Severe, unrecoverable error.
SPLINFO_USERINTREQD	This flag is optional. It shows that recovery requires action from the user.

SplMessageBox Parameter - flErrorData

flErrorData ([ULONG](#)) - input
Length of the data in bytes.

Error data:

SPLDATA_PRINTERJAM	Printer is jammed, offline, or not turned on
SPLDATA_FORMCHGREQD	Form change required
SPLDATA_CARTCHGREQD	Font cartridge change required
SPLDATA_PENCHGREQD	Pen change required
SPLDATA_DATAERROR	Data error, such as missing file
SPLDATA_UNEXPECTERROR	Unexpected DOS error
SPLDATA_OTHER	Any other error

SplMessageBox Parameter - pszText

pszText ([PSZ](#)) - input
Pointer to the text string for the message box.

SplMessageBox Parameter - pszCaption

pszCaption ([PSZ](#)) - input
Pointer to a string containing a meaningful title for the message box.

The text is centered in the title bar. If more than 40 characters are supplied, excess characters at the beginning and end of the string are not displayed.

SplMessageBox Parameter - idWindow

idWindow (ULONG) - input
Window ID of the message box window.

SplMessageBox Parameter - fsStyle

fsStyle (ULONG) - input
Bit array specifying the contents and function of the message box.

SplMessageBox Return Value - Response

Response (ULONG) - returns
Return codes.

This function returns a ULONG value (sResponse) that indicates the user's response.

MBID_ENTER	ENTER push button was selected
MBID_OK	OK push button was selected
MBID_CANCEL	CANCEL push button was selected
MBID_ABORT	ABORT push button was selected

MBID_NO	NO push button was selected
MBID_ERROR	Function not successful; an error occurred.

SplMessageBox - Parameters

pszAddress (PSZ) - input
Pointer to a string containing the logical address of the device, such as LPT1.

flErrorInfo (ULONG) - input
Error information.

One of the following flags must be set to identify where the error occurred:

SPLINFO_QPERROR	Spooler queue processor error
SPLINFO_DDERROR	Presentation driver error
SPLINFO_SPLERROR	Spooler error
SPLINFO_OTHERERROR	Any other error

One of the following flags is also set to indicate the severity of the error:

SPLINFO_INFORMATION	Information only, no error.
SPLINFO_WARNING	Warning.
SPLINFO_ERROR	Recoverable error.
SPLINFO_SEVERE	Severe, unrecoverable error.
SPLINFO_USERINTREQD	This flag is optional. It shows that recovery requires action from the user.

flErrorData (ULONG) - input
Length of the data in bytes.

Error data:

SPLDATA_PRINTERJAM	Printer is jammed, offline, or not turned on
SPLDATA_FORMCHGREQD	Form change required
SPLDATA_CARTCHGREQD	Font cartridge change required
SPLDATA_PENCHGREQD	Pen change required
SPLDATA_DATAERROR	Data error, such as missing file
SPLDATA_UNEXPECTERROR	Unexpected DOS error
SPLDATA_OTHER	Any other error

pszText (PSZ) - input
Pointer to the text string for the message box.

pszCaption (PSZ) - input
Pointer to a string containing a meaningful title for the message box.

The text is centered in the title bar. If more than 40 characters are supplied, excess characters at the beginning and end of the string are not displayed.

idWindow (ULONG) - input
Window ID of the message box window.

fsStyle (ULONG) - input
Bit array specifying the contents and function of the message box.

Response (ULONG) - returns
Return codes.

This function returns a ULONG value (sResponse) that indicates the user's response.

MBID_ENTER	ENTER push button was selected
MBID_OK	OK push button was selected
MBID_CANCEL	CANCEL push button was selected
MBID_ABORT	ABORT push button was selected
MBID_RETRY	RETRY push button was selected
MBID_IGNORE	IGNORE push button was selected
MBID_YES	YES push button was selected
MBID_NO	NO push button was selected
MBID_ERROR	Function not successful; an error occurred.

SplMessageBox - Remarks

SplMessageBox creates a message queue if the current thread does not have one.

SplMessageBox is similar to [WinMessageBox](#).

SplPurgeQueue

SplPurgeQueue - Syntax

This function removes all jobs, except any currently printing, from a print queue.

```
#define INCL_SPL /* Or use INCL_PM, */  
#include <os2.h>  
  
PSZ      pszComputerName; /* Name of computer where queue is to be purged. */  
PSZ      pszQueueName;   /* Queue name. */  
SPLERR   rc;             /* Return code. */  
  
rc = SplPurgeQueue(pszComputerName, pszQueueName);
```

SplPurgeQueue Parameter - pszComputerName

pszComputerName ([PSZ](#)) - input
Name of computer where queue is to be purged.

A NULL string specifies the local workstation.

SplPurgeQueue Parameter - pszQueueName

pszQueueName ([PSZ](#)) - input
Queue name.

SplPurgeQueue Return Value - rc

rc ([SPLERR](#)) - returns
Return code.

NO_ERROR (0)
No errors occurred.
ERROR_ACCESS_DENIED (5)
Access is denied.
ERROR_NOT_SUPPORTED (50)
This request is not supported by the network.
ERROR_BAD_NETPATH (53)
The network path cannot be located.
ERROR_INVALID_PARAMETER (87)
An invalid parameter was specified.
NERR_NetNotStarted (2102)
The network program is not started.
NERR_QNotFound (2150)
The printer queue does not exist.
NERR_SpoolerNotLoaded (2161)
The spooler is not running.
NERR_InvalidComputer (2351)
The computer name is invalid.

SplPurgeQueue - Parameters

pszComputerName ([PSZ](#)) - input
Name of computer where queue is to be purged.

A NULL string specifies the local workstation.

pszQueueName ([PSZ](#)) - input
Queue name.

rc ([SPLERR](#)) - returns
Return code.

NO_ERROR (0)
No errors occurred.
ERROR_ACCESS_DENIED (5)
Access is denied.
ERROR_NOT_SUPPORTED (50)
This request is not supported by the network.
ERROR_BAD_NETPATH (53)
The network path cannot be located.
ERROR_INVALID_PARAMETER (87)
An invalid parameter was specified.
NERR_NetNotStarted (2102)
The network program is not started.
NERR_QNotFound (2150)
The printer queue does not exist.
NERR_SpoolerNotLoaded (2161)
The spooler is not running.
NERR_InvalidComputer (2351)
The computer name is invalid.

SplPurgeQueue - Remarks

A print job that is printing is not affected by this function.

If a print queue is pending deletion when this function is made, the queue is deleted when the job that is currently printing ends.

To purge a remote queue requires administrator privilege on the remote server.

SplQmGetJobID

SplQmGetJobID - Syntax

Description:

This function returns the spooler print job ID for the spool file handle.

This function allows Presentation drivers (or applications) to get the spooler print job ID while still spooling the job. Currently, only [SplQmEndDoc](#) will return the spooler print job ID.

SplQmGetJobID will return an error if called after [SplQmEndDoc](#) and before the next [SplQmStartDoc](#) because the spool file handle does not reference a spool job after SplQmEndDoc.

```
#define INCL_SPL
#define INCL_SPLBIDI
#include <os2.h>

HSPL      hspl;          /* Spool file handle returned by SplQmOpen. */
ULONG     ulLevel;       /* Level of job information; currently, level 0 is supported. */
PVOID     pBuf;          /* Buffer to receive job information. */
ULONG     cbBuf;         /* Length of pBuf, in bytes. */
PULONG    pcbNeeded;     /* Receives length, in bytes, of buffer needed to store job information. */
ULONG     rc;            /* Return codes. */

rc = SplQmGetJobID(hspl, ulLevel, pBuf, cbBuf,
                  pcbNeeded);
```

SplQmGetJobID Parameter - hspl

hspl ([HSPL](#)) - input
Spool file handle returned by SplQmOpen.

SplQmGetJobID Parameter - ulLevel

ulLevel ([ULONG](#)) - input
Level of job information; currently, level 0 is supported.

SplQmGetJobID Parameter - pBuf

pBuf ([PVOID](#)) - output
Buffer to receive job information.

Level 0 will return the QMJOBINFO data structure.

SplQmGetJobID Parameter - cbBuf

cbBuf ([ULONG](#)) - input
Length of *pBuf*, in bytes.

SplQmGetJobID Parameter - pcbNeeded

pcbNeeded ([PULONG](#)) - output
Receives length, in bytes, of buffer needed to store job information.

SplQmGetJobID Return Value - rc

rc ([ULONG](#)) - returns
Return codes.

0	Success
ERROR_INVALID_HANDLE(6)	Invalid handle given.
ERROR_INVALID_PARAMETER(87)	<i>ulLevel</i> not 0 or invalid parameter given.
ERROR_MORE_DATA(234)	Part of the information requested was returned, but there was not enough room for all the data. The <i>*pcbOutData</i> parameter contains the size of buffer needed to retrieve all the query response data.
ERROR_NOT_SUPPORTED(50)	This function is not supported by the print server processing the spool job.
NERR_BufTooSmall(2123)	No information was returned because the output buffer was too small. <i>*pcbOutData</i> contains the size of buffer needed to retrieve all the query response data.
NERR_JobNotFound(2151)	No spooler job found.

SplQmGetJobID - Parameters

hspl ([HSPL](#)) - input
Spool file handle returned by SplQmOpen.

ulLevel ([ULONG](#)) - input
Level of job information; currently, level 0 is supported.

pBuf ([PVOID](#)) - output
Buffer to receive job information.

Level 0 will return the QMJOBINFO data structure.

cbBuf ([ULONG](#)) - input
Length of *pBuf*, in bytes.

pcbNeeded ([PULONG](#)) - output
Receives length, in bytes, of buffer needed to store job information.

rc ([ULONG](#)) - returns
Return codes.

0	Success
ERROR_INVALID_HANDLE(6)	Invalid handle given.
ERROR_INVALID_PARAMETER(87)	<i>uiLevel</i> not 0 or invalid parameter given.
ERROR_MORE_DATA(234)	Part of the information requested was returned, but there was not enough room for all the data. The <i>*pcbOutData</i> parameter contains the size of buffer needed to retrieve all the query response data.
ERROR_NOT_SUPPORTED(50)	This function is not supported by the print server processing the spool job.
NERR_BufTooSmall(2123)	No information was returned because the output buffer was too small. <i>*pcbOutData</i> contains the size of buffer needed to retrieve all the query response data.

SplQmNewPage

SplQmNewPage - Syntax

Description:

This function notifies the spooler of a page boundary when spooling a print job. It is called by the Presentation driver just prior to the first [SplQmWrite](#) for a page, including before the first page of the print job being spooled.

SplQmNewPage allows prespool approximation of the length of print jobs and may be used to alter job scheduling. The function may be called once, when the entire metafile is spooled, with the total number of pages for the print job.

This call also sets *ulPagesSpooled* in PRJINFO4 for the print job.

```
#define INCL_SPL
#define INCL_SPLBIDI
#include <os2.h>

HSPL    hspl;           /* Spool file handle returned by SplQmOpen. */
ULONG   ulPageNumber;   /* Page number of next SplQmWrite. */
ULONG   rc;             /* Return codes. */

rc = SplQmNewPage(hspl, ulPageNumber);
```

SplQmNewPage Parameter - hspl

hspl ([HSPL](#)) - input
Spool file handle returned by SplQmOpen.

SplQmNewPage Parameter - ulPageNumber

ulPageNumber ([ULONG](#)) - input
Page number of next SplQmWrite.

The first page number would be 1 (one).

SplQmNewPage Return Value - rc

rc ([ULONG](#)) - returns
Return codes.

0	Success
ERROR_INVALID_HANDLE(6)	Invalid handle given.

SplQmNewPage - Parameters

hspl ([HSPL](#)) - input
Spool file handle returned by SplQmOpen.

uiPageNumber ([ULONG](#)) - input
Page number of next SplQmWrite.

The first page number would be 1 (one).

rc ([ULONG](#)) - returns
Return codes.

0	Success
ERROR_INVALID_HANDLE(6)	Invalid handle given.

SplQmOpen

SplQmOpen - Syntax

[Description:](#)

SplQmOpen opens a spool file for generating a print job. It corresponds to the [DevOpenDC](#) call.

```
#define INCL_SPL /* Or use INCL_PM, */
#include <os2.h>

PSZ          pszToken;    /* Reserved value. */
LONG         lCount;      /* Number of items. */
```

```
PQMOPENDATA    pqmdopData; /* Pointer to DevOpenStruc. */
HSPL           hspl;       /* Spooler handle. */

hspl = SplQmOpen(pszToken, lCount, pqmdopData);
```

SplQmOpen Parameter - pszToken

pszToken (**PSZ**) - input
Reserved value.

SplQmOpen Parameter - lCount

lCount (**LONG**) - input
Number of items.

This is the number of items present in the *pqmdopData* supplied. This can be shorter than the full list, if omitted items are irrelevant.

This parameter must be greater than 0.

SplQmOpen Parameter - pqmdopData

pqmdopData (**PQMOPENDATA**) - input
Pointer to DevOpenStruc.

SplQmOpen Return Value - hspl

hspl (**HSPL**) - returns
Spooler handle.

Nonzero	Spooler handle
SPL_ERROR	Error

SplQmOpen - Parameters

pszToken ([PSZ](#)) - input
Reserved value.

ICount ([LONG](#)) - input
Number of items.

This is the number of items present in the *pqmdopData* supplied. This can be shorter than the full list, if omitted items are irrelevant.

This parameter must be greater than 0.

pqmdopData ([PQMOPENDATA](#)) - input
Pointer to DevOpenStruc.

hspl ([HSPL](#)) - returns
Spooler handle.

Nonzero	Spooler handle
SPL_ERROR	Error

SplQmOpen - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_PARM (0x1303)
A parameter to the function contained invalid data.

PMERR_SPL_INV_LENGTH_OR_COUNT (0x401A)
The length or count is invalid.

PMERR_SPL_QUEUE_NOT_FOUND (0x4024)
The spooler queue definition could not be found.

PMERR_BASE_ERROR (0x2006)
An OS/2 base error has occurred. The base error code can be accessed using the OffBinaryData field of the ERRINFO structure returned by [WinGetErrorInfo](#).

SplQmWrite

SplQmWrite - Syntax

Description:

SplQmWrite writes a buffer of data to the spool file for the print job.

```
#define INCL_SPL /* Or use INCL_PM, */
#include <os2.h>

HSPL    hspl; /* Spooler handle. */
LONG    lCount; /* Length in bytes. */
PVOID    pData; /* Buffer of data to be written to the spool file. */
BOOL    rc; /* Success indicator. */

rc = SplQmWrite(hspl, lCount, pData);
```

SplQmWrite Parameter - hspl

hspl ([HSPL](#)) - input
Spooler handle.

SplQmWrite Parameter - ICount

ICount (**LONG**) - input
Length in bytes.

This is the length of *pData*; it must not be less than 1 or greater than 65 535. Data that is longer than this must be written by two or more calls.

SplQmWrite Parameter - pData

pData (**PVOID**) - input
Buffer of data to be written to the spool file.

SplQmWrite Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

SplQmWrite - Parameters

hSpl (**HSPL**) - input
Spooler handle.

ICount (**LONG**) - input
Length in bytes.

This is the length of *pData*; it must not be less than 1 or greater than 65 535. Data that is longer than this must be written by two or more calls.

pData (**PVOID**) - input
Buffer of data to be written to the spool file.

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

SplQmWrite - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_PARM (0x1303)

A parameter to the function contained invalid data.

PMERR_BASE_ERROR (0x2006)

An OS/2 base error has occurred. The base error code can be accessed using the OffBinaryData field of the ERRINFO structure returned by [WinGetErrorInfo](#).

PMERR_SPL_INV_LENGTH_OR_COUNT (0x401A)

The length or count is invalid.

PMERR_SPL_QUEUE_ERROR (0x4004)

No spooler queue supplied or found.

PMERR_SPL_PRINT_ABORT (0x4008)

The job has already been aborted.

PMERR_STARTDOC_NOT_ISSUED (0x2104)

A request to write spooled output without first issuing a STARTDOC was attempted.

PMERR_SPL_CANNOT_OPEN_FILE (0x401C)

Unable to open the file.

PMERR_SPL_INV_HSPL (0x4005)

The spooler handle is invalid.

PMERR_SPL_NO_DISK_SPACE (0x4006)

There is not enough free disk space.

-

SplQmWrite - Example Code

This function writes a buffer of data to the spool file for the print job. The size of the data buffer must not be greater than 64KB. Print jobs that exceed the maximum buffer size must be written by repeatedly calling to this function.

```
#define INCL_SPL
#include <OS2.H>

HSPL hspl; /* spooler handle. */

SplQmWrite(hspl,
           strlen("DATA"),
           (PVOID)"DATA");
```

SplQueryControlPanel

SplQueryControlPanel - Syntax

Description:

This function queries a specific control panel DLL for support for the printer attached to the given port.

```
#define INCL_SPL
#define INCL_SPLBIDI
#include <os2.h>

PSZ      pszComputerName; /* Name of computer connected to the printer port. */
PSZ      pszPortName;    /* Printer port name. */
PSZ      pszDeviceID;    /* Device ID, if known, for the printer connected to pszPortName. */
PSZ      pszControlPanel; /* Name of control panel to call to query support for this printer. */
ULONG    flCapabilities;  /* Capabilities requested. */
PULONG   pulOptions;      /* Option value returned by the control panel DLL. */
ULONG    rc;              /* Return codes. */

rc = SplQueryControlPanel(pszComputerName,
    pszPortName, pszDeviceID, pszControlPanel,
    flCapabilities, pulOptions);
```

SplQueryControlPanel Parameter - pszComputerName

pszComputerName ([PSZ](#)) - input

Name of computer connected to the printer port.

This parameter is NULL for printers whose port exists on the current machine.

SplQueryControlPanel Parameter - pszPortName

pszPortName ([PSZ](#)) - input
Printer port name.

The name of the printer port in *pszComputerName* used to determine if a control panel can be displayed. Following is an example of a port name:
LPT1

This will be a locally defined port name.

SplQueryControlPanel Parameter - pszDeviceID

pszDeviceID ([PSZ](#)) - input
Device ID, if known, for the printer connected to *pszPortName*.

SplQueryControlPanel Parameter - pszControlPanel

pszControlPanel ([PSZ](#)) - input
Name of control panel to call to query support for this printer.

This name can be one of the following:

- The name registered with [SplRegisterControlPanel](#)
- One of the control panel names returned by [SplGetControlPanelList](#)

This parameter can be used to determine the type of support given by a control panel in the list.

SplQueryControlPanel Parameter - flCapabilities

flCapabilities ([ULONG](#)) - input
Capabilities requested.

FL_ADMIN - 0x00000001

Set if an administrator wants the control panel.

SplQueryControlPanel Parameter - pulOptions

pulOptions ([PULONG](#)) - output

Option value returned by the control panel DLL.

Values are as follows:

OPT_CUSTOM(2)

A control panel for the specific device is available.

OPT_GENERIC(1)

A generic control panel can be displayed for the printer.

SplQueryControlPanel Return Value - rc

rc ([ULONG](#)) - returns

Return codes.

0

Success

ERROR_INVALID_NAME(123)

pszName is not the name of a control panel DLL.

ERROR_NOT_SUPPORTED(50)

A control panel for this printer is not supported by the called control panel DLL.

SplQueryControlPanel - Parameters

pszComputerName ([PSZ](#)) - input

Name of computer connected to the printer port.

This parameter is NULL for printers whose port exists on the current machine.

pszPortName ([PSZ](#)) - input

Printer port name.

The name of the printer port in *pszComputerName* used to determine if a control panel can be displayed. Following is an example of a port name:

LPT1

This will be a locally defined port name.

pszDeviceID ([PSZ](#)) - input

Device ID, if known, for the printer connected to *pszPortName*.

pszControlPanel ([PSZ](#)) - input

Name of control panel to call to query support for this printer.

This name can be one of the following:

- The name registered with [SplRegisterControlPanel](#)
- One of the control panel names returned by [SplGetControlPanelList](#)

This parameter can be used to determine the type of support given by a control panel in the list.

flCapabilities ([ULONG](#)) - input
Capabilities requested.

FL_ADMIN - 0x00000001

Set if an administrator wants the control panel.

pulOptions ([PULONG](#)) - output
Option value returned by the control panel DLL.

Values are as follows:

OPT_CUSTOM(2)

A control panel for the specific device is available.

OPT_GENERIC(1)

A generic control panel can be displayed for the printer.

rc ([ULONG](#)) - returns
Return codes.

0

Success

ERROR_INVALID_NAME(123)

pszName is not the name of a control panel DLL.

ERROR_NOT_SUPPORTED(50)

A control panel for this printer is not supported by the called control panel DLL.

SplQueryControlPanel - Remarks

None.

SplQueryDevice

SplQueryDevice - Syntax

This function retrieves information about a print device.

```
#define INCL_SPL /* Or use INCL_PM, */
#include <os2.h>

PSZ      pszComputerName; /* Name of computer where print device is to be queried. */
PSZ      pszPrintDeviceName; /* Name of Print Device. */
ULONG    ulLevel; /* Level of detail required. */
PVOID    pBuf; /* Buffer. */
ULONG    cbBuf; /* Size, in bytes, of Buffer. */
PULONG    pcbNeeded; /* Size in bytes of available information. */
SPLERR    rc; /* Return code. */

rc = SplQueryDevice(pszComputerName, pszPrintDeviceName,
    ulLevel, pBuf, cbBuf, pcbNeeded);
```

SplQueryDevice Parameter - pszComputerName

pszComputerName (PSZ) - input
Name of computer where print device is to be queried.

A NULL string specifies the local workstation.

SplQueryDevice Parameter - pszPrintDeviceName

pszPrintDeviceName (PSZ) - input
Name of Print Device.

This can specify a print device name or a port name. If *ulLevel* is 0, it must be a port name. If *ulLevel* is 2 or 3, it must be a print device name.

SplQueryDevice Parameter - ulLevel

ulLevel (ULONG) - input
Level of detail required.

This must be 0, 2 or 3.

SplQueryDevice Parameter - pBuf

pBuf (PVOID) - in/out
Buffer.

The returned contents of the buffer depend on the value specified in *ulLevel* as follows:

	<i>ulLevel</i>	Buffer Contents
0		A port name consisting of 9 characters, including a null terminator.
2		A print device name of type PSZ .
3		A PRDINFO3 structure.

SplQueryDevice Parameter - cbBuf

cbBuf ([ULONG](#)) - input
Size, in bytes, of Buffer.

It must be greater than 0.

SplQueryDevice Parameter - pcbNeeded

pcbNeeded ([PULONG](#)) - output
Size in bytes of available information.

SplQueryDevice Return Value - rc

rc ([SPLERR](#)) - returns
Return code.

- NO_ERROR (0)
No errors occurred.
- ERROR_NOT_SUPPORTED (50)
This request is not supported by the network.
- ERROR_BAD_NETPATH (53)
The network path cannot be located.
- ERROR_INVALID_PARAMETER (87)
An invalid parameter is specified.
- ERROR_INVALID_LEVEL (124)
The level parameter is invalid.
- ERROR_MORE_DATA (234)
Additional data is available.
- NERR_NetNotStarted (2102)
The network program is not started.
- NERR_BufTooSmall (2123)
The API return buffer is too small.
- NERR_DestNotFound (2152)
The print device cannot be found.
- NERR_InvalidComputer (2351)
The computer name is invalid.

SplQueryDevice - Parameters

pszComputerName (PSZ) - input

Name of computer where print device is to be queried.

A NULL string specifies the local workstation.

pszPrintDeviceName (PSZ) - input

Name of Print Device.

This can specify a print device name or a port name. If *ulLevel* is 0, it must be a port name. If *ulLevel* is 2 or 3, it must be a print device name.

ulLevel (ULONG) - input

Level of detail required.

This must be 0, 2 or 3.

pBuf (PVOID) - in/out

Buffer.

The returned contents of the buffer depend on the value specified in *ulLevel* as follows:

<i>ulLevel</i>	Buffer Contents
0	A port name consisting of 9 characters, including a null terminator.
2	A print device name of type PSZ .
3	A PRDINFO3 structure.

cbBuf (ULONG) - input

Size, in bytes, of Buffer.

It must be greater than 0.

pcbNeeded (PULONG) - output

Size in bytes of available information.

rc (SPLERR) - returns

Return code.

NO_ERROR (0)

No errors occurred.

ERROR_NOT_SUPPORTED (50)

This request is not supported by the network.

ERROR_BAD_NETPATH (53)

The network path cannot be located.

ERROR_INVALID_PARAMETER (87)

An invalid parameter is specified.

ERROR_INVALID_LEVEL (124)

The level parameter is invalid.

ERROR_MORE_DATA (234)

Additional data is available.

NERR_NetNotStarted (2102)

The network program is not started.

NERR_BufTooSmall (2123)

The API return buffer is too small.

NERR_DestNotFound (2152)

The print device cannot be found.

NERR_InvalidComputer (2351)

The computer name is invalid.

SplQueryDevice - Remarks

If *ulLevel* is 0, the port name in *pBuf* is truncated to 8 characters.

If *ulLevel* is 3, and *pBuf* cannot hold the entire [PRDINFO3](#) structure, SplQueryDevice returns NERR_BufTooSmall (2123).

To obtain the size of buffer required, call `SplQueryDevice` with the required value of *ulLevel* and a NULL buffer. The number of bytes required is returned in *pcbNeeded*.

If no job is printing on the print device, bits 2-11 of *fsStatus* in the [PRDINFO3](#) data structure are meaningless.

SplQueryJob

SplQueryJob - Syntax

This function retrieves information about a print job.

```

#define INCL_SPL /* Or use INCL_PM, */
#include <os2.h>

PSZ      pszComputerName; /* Name of computer where print job is to be queried. */
PSZ      pszQueueName;   /* Queue Name. */
ULONG    ulJob;          /* Job identification number. */
ULONG    ulLevel;        /* Level of detail required. */
PVOID    pBuf;           /* Buffer. */
ULONG    cbBuf;          /* Size, in bytes, of Buffer. */
PULONG    pcbNeeded;     /* Size in bytes of available information. */
SPLERR    rc;            /* Return code. */

rc = SplQueryJob(pszComputerName, pszQueueName,
                ulJob, ulLevel, pBuf, cbBuf, pcbNeeded);

```

SplQueryJob Parameter - pszComputerName

pszComputerName (PSZ) - input
Name of computer where print job is to be queried.

A NULL string specifies the local workstation.

SplQueryJob Parameter - pszQueueName

pszQueueName (PSZ) - input
Queue Name.

SplQueryJob Parameter - ulJob

ulJob (ULONG) - input
Job identification number.

SplQueryJob Parameter - ulLevel

ulLevel (ULONG) - input
Level of detail required.

This must be 0, 2, or 3.

SplQueryJob Parameter - pBuf

pBuf (PVOID) - in/out
Buffer.

The returned contents of the buffer depend on the value specify in *ulLevel* as follow:

<i>ulLevel</i>	Buffer Contents
0	The job identifier
2	A PRJINFO2 structure, with variable information, up to the <i>cbBuf</i> of <i>pBuf</i>
3	A PRJINFO3 structure, with variable information, up to the <i>cbBuf</i> of <i>pBuf</i> .

SplQueryJob Parameter - cbBuf

cbBuf (**ULONG**) - input
Size, in bytes, of Buffer.

It must be greater than 0.

SplQueryJob Parameter - pcbNeeded

pcbNeeded (**PULONG**) - output
Size in bytes of available information.

SplQueryJob Return Value - rc

rc (**SPLERR**) - returns
Return code.

NO_ERROR (0)	No errors occurred.
ERROR_ACCESS_DENIED (5)	Access is denied.
ERROR_NOT_SUPPORTED (50)	This request is not supported by the network.
ERROR_BAD_NETPATH (53)	The network path cannot be located.

NERR_NetNotStarted (2102)	The network program is not started.
NERR_BufTooSmall (2123)	The API return buffer is too small.
NERR_JobNotFound (2151)	The print job does not exist.
NERR_SpoolerNotLoaded (2161)	The spooler is not running.
NERR_InvalidComputer (2351)	The computer name is invalid.

SplQueryJob - Parameters

pszComputerName (**PSZ**) - input
Name of computer where print job is to be queried.

A NULL string specifies the local workstation.

pszQueueName ([PSZ](#)) - input
Queue Name.

ulJob ([ULONG](#)) - input
Job identification number.

ulLevel ([ULONG](#)) - input
Level of detail required.

This must be 0, 2, or 3.

pBuf ([PVOID](#)) - in/out
Buffer.

The returned contents of the buffer depend on the value specify in *ulLevel* as follow:

<i>ulLevel</i>	Buffer Contents
0	The job identifier
2	A PRJINFO2 structure, with variable information, up to the <i>cbBuf</i> of <i>pBuf</i>
3	A PRJINFO3 structure, with variable information, up to the <i>cbBuf</i> of <i>pBuf</i> .

cbBuf ([ULONG](#)) - input
Size, in bytes, of Buffer.

It must be greater than 0.

pcbNeeded ([PULONG](#)) - output
Size in bytes of available information.

rc ([SPLERR](#)) - returns
Return code.

NO_ERROR (0)	No errors occurred.
ERROR_ACCESS_DENIED (5)	Access is denied.
ERROR_NOT_SUPPORTED (50)	This request is not supported by the network.
ERROR_BAD_NETPATH (53)	The network path cannot be located.

SplQueryPath

SplQueryPath - Syntax

Description:

This function returns the path to get printer drivers or port drivers.

When a new printer is being installed that requires a printer driver not yet installed, the print object calls this function to get the path to the print drivers.

```
#define INCL_SPL
#define INCL_SPLBIDI
#include <os2.h>

PSZ      pszComputerName;    /* Name of the computer for which a network print object is being created. */
PSZ      pszRemoteQueueName; /* Name of the remote queue the network print object is referencing. */
ULONG    ulLevel;           /* Level of information to return. */
PVOID    pBuf;              /* Receives the path to printer drivers for level 0. */
ULONG    cbBuf;              /* Length of buffer pointed to by pBuf, in bytes. */
PULONG    pcbNeeded;         /* Receives length, in bytes, of buffer needed to return path. */
ULONG    rc;                 /* Return codes. */

rc = SplQueryPath(pszComputerName, pszRemoteQueueName,
                  ulLevel, pBuf, cbBuf, pcbNeeded);
```

SplQueryPath Parameter - pszComputerName

pszComputerName (**PSZ**) - input

Name of the computer for which a network print object is being created.

This value can be NULL.

SplQueryPath Parameter - pszRemoteQueueName

pszRemoteQueueName (**PSZ**) - input

Name of the remote queue the network print object is referencing.

This value can be NULL.

SplQueryPath Parameter - ulLevel

ulLevel (**ULONG**) - input

Level of information to return.

This must be 0 (zero).

SplQueryPath Parameter - pBuf

pBuf (**PVOID**) - output
Receives the path to printer drivers for level 0.

SplQueryPath Parameter - cbBuf

cbBuf (**ULONG**) - input
Length of buffer pointed to by *pBuf*, in bytes.

SplQueryPath Parameter - pcbNeeded

pcbNeeded (**PULONG**) - output
Receives length, in bytes, of buffer needed to return path.

SplQueryPath Return Value - rc

rc (**ULONG**) - returns
Return codes.

0	Success
ERROR_NOT_SUPPORTED(50)	A path to printer drivers cannot be found.
NERR_BufTooSmall(2123)	Must call again with a bigger buffer.

SplQueryPath - Parameters

pszComputerName (**PSZ**) - input
Name of the computer for which a network print object is being created.

This value can be NULL.

pszRemoteQueueName (**PSZ**) - input
Name of the remote queue the network print object is referencing.

This value can be NULL.

uiLevel (**ULONG**) - input
Level of information to return.

This must be 0 (zero).

pBuf ([PVOID](#)) - output
Receives the path to printer drivers for level 0.

cbBuf ([ULONG](#)) - input
Length of buffer pointed to by *pBuf*, in bytes.

pcbNeeded ([PULONG](#)) - output
Receives length, in bytes, of buffer needed to return path.

rc ([ULONG](#)) - returns
Return codes.

0	Success
ERROR_NOT_SUPPORTED(50)	A path to printer drivers cannot be found.
NERR_BufTooSmall(2123)	Must call again with a bigger buffer.

SplQueryPath - Remarks

The spooler will look in the following places for the path to printer drivers:

1. The spooler will first look in the system .INI file for applicationName PM_SPOOLER_DRVSHARE. If found, the spooler will return the keyValue for keyName *pszComputerName* if it exists, or for the first keyName that exists under the applicationName.
2. The spooler will check the *pszComputerName* field for a share called PRINTDRV.
3. The spooler will check the user's logon domain LS:*ALIAS for a share called PRINTDRV.

If a path is found, the spooler will return the path to the caller. The path can be one of the following:

- An extended UNC path (LS:\\SERVER1\\PRINTDRV)
- A UNC path with additional subdirectories defined (LS:\\SERVER1\\PRINTDRV\\DIR1\\NEXT)
- A fully qualified pathname (Z:\\OS2\\SHARED)

The print object will use the path as follows:

- Look in the root of the path for packed files (.DR_)
- Look in the root of the path for unpacked files (.DRV)
- Look in the subdirectory PMDD_n from path, where *n* is the OS2 printer driver diskette number.

SplQueryPort

SplQueryPort - Syntax

Description:

This function queries information about a printer port.

```
#define INCL_SPL
#define INCL_SPLBIDI
#include <os2.h>

PSZ      pszComputerName; /* Name of the computer connected to the port. */
PSZ      pszPortName;    /* Name of the port to query. */
ULONG    ulLevel;        /* Level of information to return. */
PVOID    pBuf;           /* Receives the PRPORTINFO2 data structure. */
ULONG    cbBuf;          /* Length of buffer pointed to by pBuf, in bytes. */
PULONG    pcbNeeded;     /* Receives length, in bytes, of buffer needed to return all the port data. */
ULONG    rc;             /* Return codes. */

rc = SplQueryPort(pszComputerName, pszPortName,
                  ulLevel, pBuf, cbBuf, pcbNeeded);
```

SplQueryPort Parameter - pszComputerName

pszComputerName ([PSZ](#)) - input

Name of the computer connected to the port.

This value can be NULL for a local machine.

SplQueryPort Parameter - pszPortName

pszPortName ([PSZ](#)) - input

Name of the port to query.

SplQueryPort Parameter - ulLevel

ulLevel (**ULONG**) - input
Level of information to return.

This must be 2.

SplQueryPort Parameter - pBuf

pBuf (**PVOID**) - output
Receives the PRPORTINFO2 data structure.

SplQueryPort Parameter - cbBuf

cbBuf (**ULONG**) - input
Length of buffer pointed to by *pBuf*, in bytes.

SplQueryPort Parameter - pcbNeeded

pcbNeeded (**PULONG**) - output
Receives length, in bytes, of buffer needed to return all the port data.

SplQueryPort Return Value - rc

rc (**ULONG**) - returns
Return codes.

0	Success
ERROR_INVALID_LEVEL(124)	<i>ulLevel</i> is not 2.
ERROR_INVALID_PARAMETER(87)	An invalid parameter was specified; most likely an invalid <i>pBuf</i> value.
ERROR_MORE_DATA(234)	Not all data could fit in <i>pBuf</i> .
ERROR_NOT_SUPPORTED(50)	Command not supported on <i>pszComputerName</i> .
NERR_BufTooSmall(2123)	No data could fit in <i>pBuf</i> .

NERR_DestNotFound(2152)

The port name does not exist.

SplQueryPort - Parameters

pszComputerName ([PSZ](#)) - input

Name of the computer connected to the port.

This value can be NULL for a local machine.

pszPortName ([PSZ](#)) - input

Name of the port to query.

ulLevel ([ULONG](#)) - input

Level of information to return.

This must be 2.

pBuf ([PVOID](#)) - output

Receives the PRPORTINFO2 data structure.

cbBuf ([ULONG](#)) - input

Length of buffer pointed to by *pBuf*, in bytes.

pcbNeeded ([PULONG](#)) - output

Receives length, in bytes, of buffer needed to return all the port data.

rc ([ULONG](#)) - returns

Return codes.

0 Success

ERROR_INVALID_LEVEL(124)
ulLevel is not 2.

ERROR_INVALID_PARAMETER(87)
An invalid parameter was specified; most likely an invalid *pBuf* value.

ERROR_MORE_DATA(234)
Not all data could fit in *pBuf*.

ERROR_NOT_SUPPORTED(50)
Command not supported on *pszComputerName*.

NERR_BufTooSmall(2123)
No data could fit in *pBuf*.

NERR_DestNotFound(2152)
The port name does not exist.

SplQueryPort - Remarks

None.

SplQueryQueue

SplQueryQueue - Syntax

This function supplies information about a print queue, and, optionally, about the jobs in it.

```
#define INCL_SPL /* Or use INCL_PM, */
#include <os2.h>

PSZ      pszComputerName; /* Name of computer where queue is to be queried. */
PSZ      pszQueueName;   /* Queue name. */
ULONG    ulLevel;        /* Level of detail required. */
PVOID    pBuf;           /* Buffer. */
ULONG    cbBuf;          /* Size, in bytes, of Buffer. */
PULONG   pcbNeeded;      /* Size in bytes of available information. */
SPLERR   rc;             /* Return code. */

rc = SplQueryQueue(pszComputerName, pszQueueName,
                  ulLevel, pBuf, cbBuf, pcbNeeded);
```

SplQueryQueue Parameter - pszComputerName

pszComputerName ([PSZ](#)) - input
Name of computer where queue is to be queried.

A NULL string specifies the local workstation.

SplQueryQueue Parameter - pszQueueName

pszQueueName ([PSZ](#)) - input
Queue name.

SplQueryQueue Parameter - ulLevel

ulLevel ([ULONG](#)) - input
Level of detail required.

This must be 3, 4, 5, 6 or 7.

SplQueryQueue Parameter - pBuf

pBuf ([PVOID](#)) - in/out
Buffer.

The returned contents of the buffer depend on the value specified in *ulLevel* as follows:

<i>ulLevel</i>	Buffer Contents
3	A PRQINFO3 structure, with associated variable information up to <i>cbBuf</i> . The <i>fsType</i> bit PRQ3_TYPE_APPDEFAULT is set for the application default queue only.
4	A PRQINFO3 structure, with associated variable information, and an array of PRJINFO2 structures, one for each job in the queue, up to <i>cbBuf</i> .
5	A queue name of type PSZ .
6	A PRQINFO6 structure, with associated variable information up to <i>cbBuf</i> .
7	A PRQINFO3 structure, with associated variable information, and an array of PRJINFO4 structures, one for each job in the queue, up to <i>cbBuf</i> .

SplQueryQueue Parameter - cbBuf

cbBuf ([ULONG](#)) - input
Size, in bytes, of Buffer.

It must be greater than 0.

SplQueryQueue Parameter - pcbNeeded

pcbNeeded ([PULONG](#)) - output
Size in bytes of available information.

SplQueryQueue Return Value - rc

rc (SPLERR) - returns
Return code.

NO_ERROR (0)
No errors occurred.

ERROR_ACCESS_DENIED (5)
Access is denied.

ERROR_NOT_SUPPORTED (50)
This request is not supported by the network.

ERROR_BAD_NETPATH (53)
The network path cannot be located.

ERROR_INVALID_PARAMETER (87)
An invalid parameter is specified.

ERROR_INVALID_LEVEL (124)
The level parameter is invalid.

ERROR_MORE_DATA (234)
Additional data is available.

NERR_NetNotStarted (2102)
The network program is not started.

NERR_BufTooSmall (2123)
The API return buffer is too small.

NERR_QNotFound (2150)
The printer queue does not exist.

NERR_InvalidComputer (2351)
The computer name is invalid.

SplQueryQueue - Parameters

pszComputerName (PSZ) - input
Name of computer where queue is to be queried.

A NULL string specifies the local workstation.

pszQueueName (PSZ) - input
Queue name.

ulLevel (ULONG) - input
Level of detail required.

This must be 3, 4, 5, 6 or 7.

pBuf (PVOID) - in/out
Buffer.

The returned contents of the buffer depend on the value specified in *ulLevel* as follows:

<i>ulLevel</i>	Buffer Contents
3	A PRQINFO3 structure, with associated variable information up to <i>cbBuf</i> . The <i>fsType</i> bit PRQ3_TYPE_APPDEFAULT is set for the application default queue only.
4	A PRQINFO3 structure, with associated variable information, and an array of PRJINFO2 structures, one for each job in the queue, up to <i>cbBuf</i> .
5	A queue name of type PSZ .
6	A PRQINFO6 structure, with associated variable information up to <i>cbBuf</i> .
7	A PRQINFO3 structure, with associated variable information, and an array of PRJINFO4 structures, one for each job in the queue, up to <i>cbBuf</i> .

cbBuf (ULONG) - input

Size, in bytes, of Buffer.

It must be greater than 0.

pcbNeeded ([PULONG](#)) - output
Size in bytes of available information.

rc ([SPLERR](#)) - returns
Return code.

NO_ERROR (0)
No errors occurred.
ERROR_ACCESS_DENIED (5)
Access is denied.
ERROR_NOT_SUPPORTED (50)
This request is not supported by the network.
ERROR_BAD_NETPATH (53)
The network path cannot be located.
ERROR_INVALID_PARAMETER (87)
An invalid parameter is specified.
ERROR_INVALID_LEVEL (124)
The level parameter is invalid.
ERROR_MORE_DATA (234)
Additional data is available.
NERR_NetNotStarted (2102)
The network program is not started.
NERR_BufTooSmall (2123)
The API return buffer is too small.
NERR_QNotFound (2150)
The printer queue does not exist.
NERR_InvalidComputer (2351)
The computer name is invalid.

SplQueryQueue - Remarks

If *ulLevel* is 3 or 4, and *pBuf* cannot hold the entire [PRQINFO3](#) structure, SplQueryQueue returns NERR_BufTooSmall (2123).

If *ulLevel* is 6, and *pBuf* cannot hold the entire [PRQINFO6](#) structure, SplQueryQueue returns NERR_BufTooSmall (2123).

If *ulLevel* is 4, and *pBuf* cannot hold all the available [PRJINFO2](#) structures, SplQueryQueue returns ERROR_MORE_DATA (234).

To obtain the size of buffer required, call SplQueryQueue with the required value of *ulLevel*, *cbBuf* set to 0 (zero), and a NULL buffer. The number of bytes required is returned in *pcbNeeded*.

SplRegister

SplRegister - Syntax

Description:

This function allows applications to register for notification of events about printers. This function may be used for job accounting purposes or by printer drivers to keep aware of the operation of the print subsystem.

```
#define INCL_SPL
#define INCL_SPLBIDI
#include <os2.h>

PSZ      pszComputerName; /* Printer server name to register for alert notification. */
PSZ      pszName;         /* Case-sensitive name of printer port to register for alerts. */
HWND     hwndNotify;      /* Window handle to get notify messages. */
ULONG     ulCategory;     /* Category of alert to register. */
ULONG     ulType;         /* Type of alert to enable for the given category. */
PULONG    pulHandle;      /* Pointer to spooler alert handle. */
ULONG     rc;             /* Return codes. */

rc = SplRegister(pszComputerName, pszName,
                hwndNotify, ulCategory, ulType, pulHandle);
```

SplRegister Parameter - pszComputerName

pszComputerName ([PSZ](#)) - input

Printer server name to register for alert notification.

The field is used by an application running on a client machine to register for alerts on a print server. To register locally, this field must be NULL.

SplRegister Parameter - pszName

pszName ([PSZ](#)) - input

Case-sensitive name of printer port to register for alerts.

This value can be a virtual port name.

SplRegister Parameter - hwndNotify

hwndNotify ([HWND](#)) - input

Window handle to get notify messages.

The message posted is as follows:

Message ID is WM_SPOOLER_ALERT(0x00d8)

MP1 will define the type of alert as follows:

```

/* Alert type - SHORT1FROMMP(MP1) bits 0-7 */
#define SPLMSG_SPECIAL_ALERT      0x00FC
#define SPLMSG_EXTENDED_ALERT    0x00FD
#define SPLMSG_CORE_ALERT_MASK   0x00FF

/* Extended alert type - SHORT1FROMMP(MP1) bits 8-15 */
#define SPLMSG_EXTENDED_TYPE_MASK 0xFF00

```

If the object type is SPLMSG_EXTENDED_ALERT, then this is an extended alert. The extended alert category is SHORT2FROMMP(MP1). The type of alert in the given extended alert category is SHORT1FROMMP(MP1) bits 8-15. This limits the notification given to applications registered for extended alerts to only the specific categories that are 0xFFFF or less and to only category types that are 0xFF or less.

If the object type is SPLMSG_SPECIAL_ALERT, then this is a special alert generated by the spooler and SHORT2FROMMP(MP1) will contain one of the following messages:

SPLMSG_CONNECTION_LOST - 0x0002
Connection to computer terminated; all alerts disabled for given computer.

SPLMSG_PORT_TERMINATED - 0x0003
Registration terminated for port.

SPLMSG_SPOOLER_DISABLED - 0x0001
Spooler disabled; all alerts for given computer are disabled.

If the object type is less than SPLMSG_SPECIAL_ALERT(0xFC), then this is a core alert. The specific core alert posted will be: SHORT1FROMMP(MP1) bits 0-7(SPLMSG_CORE_ALERT_MASK)

If the core alert is PRTALERT_TYPE_PAGE_PRINTED(9), then SHORT1FROMMP(MP1) bits 8-15(SPLMSG_PAGE_PRINTED_MASK) will be the page number printed. If the page number is above 255, the value hex 'FF' will be put in this byte field.

If the core alert is **not** PRTALERT_TYPE_PAGE_PRINTED(9), then SHORT1FROMMP(MP1) bits 8-15(SPLMSG_CORE_SEVERITY_MASK) will be the severity of the alert. SHORT2FROMMP(MP1) will be the spooler job ID if this is a core alert for a print job.

The core alert type will be one of the following:

Value	Description
1	PRTALERT_TYPE_INPUT Input alert (Example: out of paper).
2	PRTALERT_TYPE_OUTPUT Output alert (Example: output bin full).
3	PRTALERT_TYPE_JAM Paper jam alert.
4	PRTALERT_TYPE_OPERATOR Operator intervention required (Example: print ribbon jam).
5	PRTALERT_TYPE_CONFIG_CHANGE Configuration changed (Example: cartridge removed).
6	PRTALERT_TYPE_SUPPLIES Supplies alert (Example: out of toner).
7	PRTALERT_TYPE_JOB_START Job started printing.
8	PRTALERT_TYPE_JOB_STACKED Job completed and stacked.
9	PRTALERT_TYPE_PAGE_PRINTED Page printed.
10	PRTALERT_TYPE_JOB_CANCELLED Job cancelled inside printer.
11	PRTALERT_TYPE_JOB_HELD Job held inside printer.

12	PRTALERT_TYPE_COVER_OPEN Cover or panel open.
13	PRTALERT_TYPE_POWER_ON Printer powered on.
14	PRTALERT_TYPE_RESET Printer reset.
15	PRTALERT_TYPE_ONLINE Printer now online.
16	PRTALERT_TYPE_OFFLINE Printer now offline.
17	PRTALERT_TYPE_TIMED_ALERT Timed alert.
18	PRTALERT_TYPE_COMMUNICATION_PROBLEM Communication problem.
19	PRTALERT_TYPE_COMM_STATUS_CHANGED Communication status changed. BIDI_Q_PORT should be issued to get current state.
0xFF	PRTALERT_TYPE_OTHER Other alert type (0xFFFFFFFF).

The severity of the problem will be one of the following:

Value	Description
00	PRTALERT_SEV_INFORMATIONAL
01	PRTALERT_SEV_WARNING
02	PRTALERT_SEV_ERROR Printing stopped due to error.
03	PRTALERT_SEV_SERVICE Service is required.
04 - FD	Reserved
FE	PRTALERT_SEV_OTHER Other (0xFE)
FF	PRTALERT_SEV_UNKNOWN Unknown (0xFF)

MP2 contents are as follows:

SHORT1FROMMP(MP1) is the atomized print server name.

If the notification is from the local spooler, this value will be zero.

SHORT2FROMMP(MP2) is the atomized print queue name when the message involves a print job (alert values 7 - 11); otherwise, it will be the atomized printer port name, if applicable.

SplRegister Parameter - ulCategory

ulCategory (**ULONG**) - input

Category of alert to register.

This value can be the core alert category or an extended alert category as defined below:

PRTALERT_CATEGORY_CORE - 0x00000001
Core alert category

PRTALERT_CATEGORY_EXTENDED - 0x0000D000
Beginning of the extended alert categories. Protocol converters should limit the category range to between 0x0000D000 and 0x0000DFFF.

PRTALERT_CATEGORY_EXT_MAX - 0x0000DFFF
End of the extended alert categories.

If the protocol converter does not support the given category, ERROR_INVALID_CATEGORY(117) is returned.

SplRegister Parameter - ulType

ulType (ULONG) - input
Type of alert to enable for the given category.

If the category is PRTALERT_CATEGORY_CORE, this is a bit-field that defines the additional core alerts to enable. The core alerts corresponding to the bits set in the *ulType* field will be enabled, in addition to any currently enabled core alerts. If the protocol converter does not understand one of the bits that are set, ERROR_INVALID_FLAG_NUMBER(186) should be returned.

If the printer is not capable of setting one of the core alerts whose bit is set, and if any core alerts can be enabled, a Success return code should be returned.

If the category is **not** PRTALERT_CATEGORY_CORE, then this is a value that defines the specific extended alert to enable.

Bit definitions for core alerts are as follows:

Bit	Description
0	PRTALERT_CORE_INPUT - 0x00000001 Input alert (Example: out of paper).
1	PRTALERT_CORE_OUTPUT - 0x00000002 Output alert (Example: output bin is full).
2	PRTALERT_CORE_JAM - 0x00000004 Paper jam alert.
3	PRTALERT_CORE_OPERATOR - 0x00000008 Operator intervention required (Example: print ribbon jam).
4	PRTALERT_CORE_CONFIG_CHANGE - 0x00000010 Configuration changed (Example: cartridge removed).
5	PRTALERT_CORE_SUPPLIES - 0x00000020 Supplies alert (Example: out of toner).
6	PRTALERT_CORE_JOB_START - 0x00000040 Job started printing.
7	PRTALERT_CORE_JOB_STACKED - 0x00000080 Job completed and stacked.
8	PRTALERT_CORE_PAGE_PRINTED - 0x00000100 Page printed.
9	PRTALERT_CORE_JOB_CANCELLED - 0x00000200 Job cancelled inside printer.
10	PRTALERT_CORE_JOB_HELD - 0x00000400 Job held inside printer.
11	PRTALERT_CORE_COVER_OPEN - 0x00000800

	Cover or panel open.
12	PRTALERT_CORE_POWER_ON - 0x00001000 Printer powered on.
13	PRTALERT_CORE_RESET - 0x00002000 Printer reset.
14	PRTALERT_CORE_ONLINE - 0x00004000 Printer now online.
15	PRTALERT_CORE_OFFLINE - 0x00008000 Printer now offline.
16	PRTALERT_CORE_TIMED_ALERT - 0x00010000 Timed alert.
17	PRTALERT_CORE_COMMUNICATION_PROBLEM - 0x00020000 Communication problem.
18	PRTALERT_CORE_COMM_STATUS_CHANGED - 0x00040000 Communication status changed.

SplRegister Parameter - pulHandle

pulHandle ([PULONG](#)) - in/out
Pointer to spooler alert handle.

For initial registration, the value pointed to by this parameter should be 0 (zero). If an application wants to make better use of spooler resources, the application can use the same returned spooler handle for all of its alert registration.

SplRegister Return Value - rc

rc ([ULONG](#)) - returns
Return codes.

0	Success
ERROR_INVALID_CATEGORY(117)	The protocol converter does not support the extended alert category.
ERROR_INVALID_FLAG_NUMBER(186)	The protocol converter did not understand a core alert that was set.
ERROR_INVALID_HANDLE(6)	The value pointed to by <i>pulHandle</i> is not a valid spooler alert handle. The value at <i>*pulHandle</i> should be set to 0 (zero) to allocate a new spooler alert handle.
ERROR_INVALID_PARAMETER(87)	An invalid buffer given.
ERROR_NOT_SUPPORTED(50)	The spooler on the given print server cannot support alert notification.
PMERR_SPL_SPOOLER_NOT_INSTALLED(0x4009)	The spooler is not enabled.

SplRegister - Parameters

pszComputerName (PSZ) - input

Printer server name to register for alert notification.

The field is used by an application running on a client machine to register for alerts on a print server. To register locally, this field must be NULL.

pszName (PSZ) - input

Case-sensitive name of printer port to register for alerts.

This value can be a virtual port name.

hwndNotify (HWND) - input

Window handle to get notify messages.

The message posted is as follows:

Message ID is WM_SPOOLER_ALERT(0x00d8)

MP1 will define the type of alert as follows:

```
/* Alert type - SHORT1FROMMP(MP1) bits 0-7 */
#define SPLMSG_SPECIAL_ALERT      0x00FC
#define SPLMSG_EXTENDED_ALERT    0x00FD
#define SPLMSG_CORE_ALERT_MASK   0x00FF

/* Extended alert type - SHORT1FROMMP(MP1) bits 8-15 */
#define SPLMSG_EXTENDED_TYPE_MASK 0xFF00
```

If the object type is SPLMSG_EXTENDED_ALERT, then this is an extended alert. The extended alert category is SHORT2FROMMP(MP1). The type of alert in the given extended alert category is SHORT1FROMMP(MP1) bits 8-15. This limits the notification given to applications registered for extended alerts to only the specific categories that are 0xFFFF or less and to only category types that are 0xFF or less.

If the object type is SPLMSG_SPECIAL_ALERT, then this is a special alert generated by the spooler and SHORT2FROMMP(MP1) will contain one of the following messages:

SPLMSG_CONNECTION_LOST - 0x0002
Connection to computer terminated; all alerts disabled for given computer.

SPLMSG_PORT_TERMINATED - 0x0003
Registration terminated for port.

SPLMSG_SPOOLER_DISABLED - 0x0001
Spooler disabled; all alerts for given computer are disabled.

If the object type is less than SPLMSG_SPECIAL_ALERT(0xFC), then this is a core alert. The specific core alert posted will be: SHORT1FROMMP(MP1) bits 0-7(SPLMSG_CORE_ALERT_MASK)

If the core alert is PRTALERT_TYPE_PAGE_PRINTED(9), then SHORT1FROMMP(MP1) bits 8-15(SPLMSG_PAGE_PRINTED_MASK) will be the page number printed. If the page number is above 255, the value hex 'FF' will be put in this byte field.

If the core alert is **not** PRTALERT_TYPE_PAGE_PRINTED(9), then SHORT1FROMMP(MP1) bits 8-15(SPLMSG_CORE_SEVERITY_MASK) will be the severity of the alert. SHORT2FROMMP(MP1) will be the spooler job ID if this is a core alert for a print job.

The core alert type will be one of the following:

Value	Description
1	PRTALERT_TYPE_INPUT Input alert (Example: out of paper).

2	PRTALERT_TYPE_OUTPUT Output alert (Example: output bin full).
3	PRTALERT_TYPE_JAM Paper jam alert.
4	PRTALERT_TYPE_OPERATOR Operator intervention required (Example: print ribbon jam).
5	PRTALERT_TYPE_CONFIG_CHANGE Configuration changed (Example: cartridge removed).
6	PRTALERT_TYPE_SUPPLIES Supplies alert (Example: out of toner).
7	PRTALERT_TYPE_JOB_START Job started printing.
8	PRTALERT_TYPE_JOB_STACKED Job completed and stacked.
9	PRTALERT_TYPE_PAGE_PRINTED Page printed.
10	PRTALERT_TYPE_JOB_CANCELLED Job cancelled inside printer.
11	PRTALERT_TYPE_JOB_HELD Job held inside printer.
12	PRTALERT_TYPE_COVER_OPEN Cover or panel open.
13	PRTALERT_TYPE_POWER_ON Printer powered on.
14	PRTALERT_TYPE_RESET Printer reset.
15	PRTALERT_TYPE_ONLINE Printer now online.
16	PRTALERT_TYPE_OFFLINE Printer now offline.
17	PRTALERT_TYPE_TIMED_ALERT Timed alert.
18	PRTALERT_TYPE_COMMUNICATION_PROBLEM Communication problem.
19	PRTALERT_TYPE_COMM_STATUS_CHANGED Communication status changed. BIDI_Q_PORT should be issued to get current state.
0xFF	PRTALERT_TYPE_OTHER Other alert type (0xFFFFFFFF).

The severity of the problem will be one of the following:

Value	Description
00	PRTALERT_SEV_INFORMATIONAL
01	PRTALERT_SEV_WARNING
02	PRTALERT_SEV_ERROR Printing stopped due to error.
03	PRTALERT_SEV_SERVICE Service is required.
04 - FD	Reserved

FE	PRTALERT_SEV_OTHER Other (0xFE)
FF	PRTALERT_SEV_UNKNOWN Unknown (0xFF)

MP2 contents are as follows:

SHORT1FROMMP(MP1) is the atomized print server name.

If the notification is from the local spooler, this value will be zero.

SHORT2FROMMP(MP2) is the atomized print queue name when the message involves a print job (alert values 7 - 11); otherwise, it will be the atomized printer port name, if applicable.

ulCategory (ULONG) - input

Category of alert to register.

This value can be the core alert category or an extended alert category as defined below:

PRTALERT_CATEGORY_CORE - 0x00000001
Core alert category

PRTALERT_CATEGORY_EXTENDED - 0x0000D000
Beginning of the extended alert categories. Protocol converters should limit the category range to between 0x0000D000 and 0x0000DFFF.

PRTALERT_CATEGORY_EXT_MAX - 0x0000DFFF
End of the extended alert categories.

If the protocol converter does not support the given category, ERROR_INVALID_CATEGORY(117) is returned.

ulType (ULONG) - input

Type of alert to enable for the given category.

If the category is PRTALERT_CATEGORY_CORE, this is a bit-field that defines the additional core alerts to enable. The core alerts corresponding to the bits set in the *ulType* field will be enabled, in addition to any currently enabled core alerts. If the protocol converter does not understand one of the bits that are set, ERROR_INVALID_FLAG_NUMBER(186) should be returned.

If the printer is not capable of setting one of the core alerts whose bit is set, and if any core alerts can be enabled, a Success return code should be returned.

If the category is **not** PRTALERT_CATEGORY_CORE, then this is a value that defines the specific extended alert to enable.

Bit definitions for core alerts are as follows:

Bit	Description
0	PRTALERT_CORE_INPUT - 0x00000001 Input alert (Example: out of paper).
1	PRTALERT_CORE_OUTPUT - 0x00000002 Output alert (Example: output bin is full).
2	PRTALERT_CORE_JAM - 0x00000004 Paper jam alert.
3	PRTALERT_CORE_OPERATOR - 0x00000008 Operator intervention required (Example: print ribbon jam).
4	PRTALERT_CORE_CONFIG_CHANGE - 0x00000010 Configuration changed (Example: cartridge removed).
5	PRTALERT_CORE_SUPPLIES - 0x00000020 Supplies alert (Example: out of toner).
6	PRTALERT_CORE_JOB_START - 0x00000040 Job started printing.
7	PRTALERT_CORE_JOB_STACKED - 0x00000080 Job completed and stacked.
8	PRTALERT_CORE_PAGE_PRINTED - 0x00000100

	Page printed.
9	PRTALERT_CORE_JOB_CANCELLED - 0x00000200 Job cancelled inside printer.
10	PRTALERT_CORE_JOB_HELD - 0x00000400 Job held inside printer.
11	PRTALERT_CORE_COVER_OPEN - 0x00000800 Cover or panel open.
12	PRTALERT_CORE_POWER_ON - 0x00001000 Printer powered on.
13	PRTALERT_CORE_RESET - 0x00002000 Printer reset.
14	PRTALERT_CORE_ONLINE - 0x00004000 Printer now online.
15	PRTALERT_CORE_OFFLINE - 0x00008000 Printer now offline.
16	PRTALERT_CORE_TIMED_ALERT - 0x00010000 Timed alert.
17	PRTALERT_CORE_COMMUNICATION_PROBLEM - 0x00020000 Communication problem.
18	PRTALERT_CORE_COMM_STATUS_CHANGED - 0x00040000 Communication status changed.

pulHandle (**PULONG**) - in/out
Pointer to spooler alert handle.

For initial registration, the value pointed to by this parameter should be 0 (zero). If an application wants to make better use of spooler resources, the application can use the same returned spooler handle for all of its alert registration.

rc (**ULONG**) - returns
Return codes.

0	Success
ERROR_INVALID_CATEGORY(117)	The protocol converter does not support the extended alert category.
ERROR_INVALID_FLAG_NUMBER(186)	The protocol converter did not understand a core alert that was set.
ERROR_INVALID_HANDLE(6)	The value pointed to by <i>pulHandle</i> is not a valid spooler alert handle. The value at <i>*pulHandle</i> should be set to 0 (zero) to allocate a new spooler alert handle.
ERROR_INVALID_PARAMETER(87)	An invalid buffer given.
ERROR_NOT_SUPPORTED(50)	The spooler on the given print server cannot support alert notification.
PMERR_SPL_SPOOLER_NOT_INSTALLED(0x4009)	The spooler is not enabled.

SpIRegister - Remarks

Note:

Registration is **not** maintained across reboots.

Any new registration is in addition to existing registration(s) for the spooler handle passed in (if any handle was passed).

To remove registration, use [SplUnRegister](#).

For each spooler alert handle, only the **last** *hwnd/Notify* passed in with the alert handle will be posted with alert messages.

That is, if you register window handle X and receive alert handle 1, then register for more alerts using window handle Y and alert handle 1, window handle Y will get alerts for alert handle 1, but window handle X will not get any alert messages.

Registration for alerts from a client on a print server requires that the user logged onto the client have authority to open a named pipe on the server. This access is normally granted to those users who have access to the print queue on a server.

SplRegisterControlPanel

SplRegisterControlPanel - Syntax

Description:

This function registers a DLL with the spooler that can display a control panel for printers. By default, all protocol converters will be checked for control panel support, so converters must not register themselves using this API.

[illegible]

SplRegisterControlPanel Parameter - pszName

pszName ([PSZ](#)) - input
Name of control panel.

This name must not conflict with any installed protocol converter name or control panel name.

SplRegisterControlPanel Parameter - pszDllPath

pszDllPath ([PSZ](#)) - input
Fully qualified path to the DLL that exports the control panel APIs.

SplRegisterControlPanel Parameter - ulFlags

ulFlags ([ULONG](#)) - input
Must be 0 (zero).

SplRegisterControlPanel Parameter - pszReserved

pszReserved ([PSZ](#)) - input
Must be NULL.

SplRegisterControlPanel Parameter - ulVersion

ulVersion ([ULONG](#)) - input
Must be 0 (zero).

SplRegisterControlPanel Return Value - rc

rc ([ULONG](#)) - returns
Return codes.

0	Success
ERROR_INVALID_LEVEL(124)	<i>ulVersion</i> not 0.
ERROR_INVALID_NAME(123)	<i>pszName</i> is already used by a protocol converter or another control panel DLL.
ERROR_INVALID_PARAMETER(87)	<i>ulFlags</i> not 0 or invalid parameter given.
ERROR_MOD_NOT_FOUND(126)	Invalid path to DLL.
ERROR_PROC_NOT_FOUND(127)	<i>pszDllPath</i> does not export the two APIs for control panels (apiref refid=spqucp form=textonly. and SplDisplayControlPanel).

SplRegisterControlPanel - Parameters

pszName ([PSZ](#)) - input
Name of control panel.

This name must not conflict with any installed protocol converter name or control panel name.

pszDllPath ([PSZ](#)) - input
Fully qualified path to the DLL that exports the control panel APIs.

ulFlags ([ULONG](#)) - input
Must be 0 (zero).

pszReserved ([PSZ](#)) - input
Must be NULL.

ulVersion ([ULONG](#)) - input
Must be 0 (zero).

rc ([ULONG](#)) - returns
Return codes.

0	Success
ERROR_INVALID_LEVEL(124)	<i>ulVersion</i> not 0.
ERROR_INVALID_NAME(123)	<i>pszName</i> is already used by a protocol converter or another control panel DLL.
ERROR_INVALID_PARAMETER(87)	<i>ulFlags</i> not 0 or invalid parameter given.
ERROR_MOD_NOT_FOUND(126)	Invalid path to DLL.
ERROR_PROC_NOT_FOUND(127)	<i>pszDllPath</i> does not export the two APIs for control panels (apiref refid=spqucp form=textonly. and SplDisplayControlPanel).

SplRegisterControlPanel - Remarks

A control panel need register itself only once; registration is maintained across reboots.

SplReleaseJob

SplReleaseJob - Syntax

This function releases a held print job.

```
#define INCL_SPL /* Or use INCL_PM, */
#include <os2.h>

PSZ      pszComputerName; /* Name of computer where job is to be continued. */
PSZ      pszQueueName;    /* Queue Name. */
ULONG    ulJob;           /* Job identification number. */
SPLERR   rc;              /* Return code. */

rc = SplReleaseJob(pszComputerName, pszQueueName,
                  ulJob);
```

SplReleaseJob Parameter - pszComputerName

pszComputerName ([PSZ](#)) - input
Name of computer where job is to be continued.

A NULL string specifies the local workstation.

SplReleaseJob Parameter - pszQueueName

pszQueueName (PSZ) - input
Queue Name.

SplReleaseJob Parameter - ulJob

ulJob (ULONG) - input
Job identification number.

SplReleaseJob Return Value - rc

rc (SPLERR) - returns
Return code.

- NO_ERROR (0)
No errors occurred.
- ERROR_ACCESS_DENIED (5)
Access is denied.
- ERROR_NOT_SUPPORTED (50)
This request is not supported by the network.
- ERROR_BAD_NETPATH (53)
The network path cannot be located.
- NERR_NetNotStarted (2102)
The network program is not started.
- NERR_JobNotFound (2151)
The print job does not exist.
- NERR_SpoolerNotLoaded (2161)
The spooler is not running.
- NERR_JobInvalidState (2164)
This operation cannot be performed on the print job in its current state.
- NERR_InvalidComputer (2351)
The computer name is invalid.

SplReleaseJob - Parameters

pszComputerName (PSZ) - input
Name of computer where job is to be continued.

A NULL string specifies the local workstation.

pszQueueName (PSZ) - input
Queue Name.

ulJob (ULONG) - input
Job identification number.

rc (SPLERR) - returns
Return code.

- NO_ERROR (0)
No errors occurred.
- ERROR_ACCESS_DENIED (5)

Access is denied.
ERROR_NOT_SUPPORTED (50)
This request is not supported by the network.
ERROR_BAD_NETPATH (53)
The network path cannot be located.
NERR_NetNotStarted (2102)
The network program is not started.
NERR_JobNotFound (2151)
The print job does not exist.
NERR_SpoolerNotLoaded (2161)
The spooler is not running.
NERR_JobInvalidState (2164)
This operation cannot be performed on the print job in its current state.
NERR_InvalidComputer (2351)
The computer name is invalid.

SplReleaseJob - Remarks

Any job can be released by a user with administrator privilege.

A job created locally can be released locally regardless of user privilege level, but it can be released remotely only by a user with administrator privilege.

A remote job can be released by a user without administrator privilege only if the user identification of the person initiating the request is the same as the user identification of the person who created the job.

SplReleaseQueue

SplReleaseQueue - Syntax

This function releases a held print queue.

```

#define INCL_SPL /* Or use INCL_PM, */
#include <os2.h>

PSZ      pszComputerName; /* Name of computer where queue is to be continued. */
PSZ      pszQueueName;    /* Queue name. */
SPLERR   rc;              /* Return code. */

rc = SplReleaseQueue(pszComputerName, pszQueueName);

```

SplReleaseQueue Parameter - pszComputerName

pszComputerName ([PSZ](#)) - input
Name of computer where queue is to be continued.

A NULL string specifies the local workstation.

SplReleaseQueue Parameter - pszQueueName

pszQueueName ([PSZ](#)) - input
Queue name.

SplReleaseQueue Return Value - rc

rc ([SPLERR](#)) - returns
Return code.

NO_ERROR (0)	No errors occurred.
ERROR_ACCESS_DENIED (5)	Access is denied.
ERROR_NOT_SUPPORTED (50)	This request is not supported by the network.
ERROR_BAD_NETPATH (53)	The network path cannot be located.
NERR_NetNotStarted (2102)	The network program is not started.
NERR_QNotFound (2150)	The printer queue does not exist.
NERR_InvalidComputer (2351)	The computer name is invalid.

SplReleaseQueue - Parameters

pszComputerName ([PSZ](#)) - input
Name of computer where queue is to be continued.

A NULL string specifies the local workstation.

pszQueueName ([PSZ](#)) - input
Queue name.

rc ([SPLERR](#)) - returns
Return code.

NO_ERROR (0)	No errors occurred.
ERROR_ACCESS_DENIED (5)	Access is denied.
ERROR_NOT_SUPPORTED (50)	

This request is not supported by the network.
ERROR_BAD_NETPATH (53)
 The network path cannot be located.
NERR_NetNotStarted (2102)
 The network program is not started.
NERR_QNotFound (2150)
 The printer queue does not exist.
NERR_InvalidComputer (2351)
 The computer name is invalid.

SplReleaseQueue - Remarks

This function releases a queue that has been held by a [SplHoldQueue](#) function, or disabled by an error on the queue. It does not affect an active print queue.

To release a queue on a remote server requires administrator privilege on the remote server.

SplSetDevice

SplSetDevice - Syntax

This function modifies the configuration of a print device.

```

#define INCL_SPL /* Or use INCL_PM, */
#include <os2.h>

PSZ      pszComputerName; /* Name of computer where print device is to be modified. */
PSZ      pszPrintDeviceName; /* Name of Print Device. */
ULONG    ulLevel; /* Level of detail required. */
PVOID    pBuf; /* Buffer. */
ULONG    cbBuf; /* Size, in bytes, of Buffer. */
ULONG    ulParmNum; /* Parameter number. */
SPLERR    rc; /* Return code. */

rc = SplSetDevice(pszComputerName, pszPrintDeviceName,
    ulLevel, pBuf, cbBuf, ulParmNum);

```

SplSetDevice Parameter - pszComputerName

pszComputerName (PSZ) - input
Name of computer where print device is to be modified.

A NULL string specifies the local workstation.

SplSetDevice Parameter - pszPrintDeviceName

pszPrintDeviceName (PSZ) - input
Name of Print Device.

SplSetDevice Parameter - ulLevel

ulLevel (ULONG) - input
Level of detail required.

This must be 3.

SplSetDevice Parameter - pBuf

pBuf (PVOID) - input
Buffer.

If *ulParmNum* is 0, this parameter must contain a complete PRJINFO3 structure Otherwise,it must contain a valid new value for the parameter of the PRJINFO3 structure indicated in *ulParmNum*

SplSetDevice Parameter - cbBuf

cbBuf (ULONG) - input
Size, in bytes, of Buffer.

It must be grater than 0.

SplSetDevice Parameter - ulParmNum

ulParmNum (ULONG) - input
Parameter number.

Specifies either that the entire [PRDINFO3](#) structure is to be modified, or only one specific parameter is to be modified.

If *ulParmNum* is 0, *pBuf* must contain a complete [PRDINFO3](#) structure. Otherwise, *pBuf* must contain a new valid value for the parameter to be modified.

The following are the possible values for this parameter:

Parameter	Constant (Value)
<i>pszLogAddr</i>	PRD_LOGADDR_PARMNUM (3)
<i>pszComment</i>	PRD_COMMENT_PARMNUM (7)
<i>pszDrivers</i>	PRD_DRIVERS_PARMNUM (8)
<i>usTimeOut</i>	PRD_TIMEOUT_PARMNUM (10)

SplSetDevice Return Value - rc

rc ([SPLERR](#)) - returns

Return code.

NO_ERROR (0)	No errors occurred.
ERROR_ACCESS_DENIED (5)	Access is denied.
ERROR_NOT_SUPPORTED (50)	This request is not supported by the network.
ERROR_BAD_NETPATH (53)	The network path cannot be located.
ERROR_INVALID_PARAMETER (87)	An invalid parameter is specified.
ERROR_INVALID_LEVEL (124)	The level parameter is invalid.
NERR_NetNotStarted (2102)	The network program is not started.
NERR_BufTooSmall (2123)	The API return buffer is too small.
NERR_DestNotFound (2152)	The print device cannot be found.
NERR_DestInvalidState (2162)	This operation cannot be performed on the print device.
NERR_SpoolNoMemory (2165)	A spooler memory allocation failure occurred.
NERR_DriverNotFound (2166)	The device driver does not exist.
NERR_BadDev (2341)	The requested device is invalid.
NERR_InvalidComputer (2351)	The computer name is invalid.

SplSetDevice - Parameters

pszComputerName ([PSZ](#)) - input

Name of computer where print device is to be modified.

A NULL string specifies the local workstation.

pszPrintDeviceName ([PSZ](#)) - input

Name of Print Device.

ulLevel (**ULONG**) - input
Level of detail required.

This must be 3.

pBuf (**PVOID**) - input
Buffer.

If *ulParmNum* is 0, this parameter must contain a complete **PRJINFO3** structure. Otherwise, it must contain a valid new value for the parameter of the **PRJINFO3** structure indicated in *ulParmNum*.

cbBuf (**ULONG**) - input
Size, in bytes, of Buffer.

It must be greater than 0.

ulParmNum (**ULONG**) - input
Parameter number.

Specifies either that the entire **PRDINFO3** structure is to be modified, or only one specific parameter is to be modified.

If *ulParmNum* is 0, *pBuf* must contain a complete **PRDINFO3** structure. Otherwise, *pBuf* must contain a new valid value for the parameter to be modified.

The following are the possible values for this parameter:

Parameter	Constant (Value)
<i>pszLogAddr</i>	PRD_LOGADDR_PARMNUM (3)
<i>pszComment</i>	PRD_COMMENT_PARMNUM (7)
<i>pszDrivers</i>	PRD_DRIVERS_PARMNUM (8)
<i>usTimeOut</i>	PRD_TIMEOUT_PARMNUM (10)

rc (**SPLERR**) - returns
Return code.

NO_ERROR (0)	No errors occurred.
ERROR_ACCESS_DENIED (5)	Access is denied.
ERROR_NOT_SUPPORTED (50)	This request is not supported by the network.
ERROR_BAD_NETPATH (53)	The network path cannot be located.
ERROR_INVALID_PARAMETER (87)	An invalid parameter is specified.
ERROR_INVALID_LEVEL (124)	The level parameter is invalid.
NERR_NetNotStarted (2102)	The network program is not started.
NERR_BufTooSmall (2123)	The API return buffer is too small.
NERR_DestNotFound (2152)	The print device cannot be found.
NERR_DestInvalidState (2162)	This operation cannot be performed on the print device.
NERR_SpoolNoMemory (2165)	A spooler memory allocation failure occurred.
NERR_DriverNotFound (2166)	The device driver does not exist.
NERR_BadDev (2341)	The requested device is invalid.
NERR_InvalidComputer (2351)	The computer name is invalid.

SplSetDevice - Remarks

This function allows modification of a print device and its connection to a logical address. To disconnect a print device from a port, use

ulLevel=3, *ulParmNum*=3, and *pBuf* is a NULL string.

To modify a print device on a remote server requires administrator privilege.

SplSetJob

SplSetJob - Syntax

This function modifies the instructions for a print job.

```
#define INCL_SPL /* Or use INCL_PM, */
```

```
#include <os2.h>

PSZ      pszComputerName; /* Name of computer where job is to be modified. */
PSZ      pszQueueName;   /* Queue Name. */
ULONG    ulJob;           /* Job identification number. */
ULONG    ulLevel;         /* Level of detail required. */
PVOID    pBuf;            /* Buffer. */
ULONG    cbBuf;           /* Size, in bytes, of Buffer. */
ULONG    ulParmNum;       /* Parameter number. */
SPLERR    rc;             /* Return code. */

rc = SplSetJob(pszComputerName, pszQueueName,
               ulJob, ulLevel, pBuf, cbBuf, ulParmNum);
```

SplSetJob Parameter - pszComputerName

pszComputerName (PSZ) - input
Name of computer where job is to be modified.

A NULL string specifies the local workstation.

SplSetJob Parameter - pszQueueName

pszQueueName (PSZ) - input
Queue Name.

SplSetJob Parameter - ulJob

ulJob (ULONG) - input
Job identification number.

SplSetJob Parameter - ulLevel

ulLevel (ULONG) - input
Level of detail required.

This must be 3.

SplSetJob Parameter - pBuf

pBuf ([PVOID](#)) - input
Buffer.

If *ulParmNum* is 0, this parameter must contain a complete [PRJINFO3](#) structure. Otherwise, it must contain a valid new value for the parameter of the [PRJINFO3](#) structure, indicated in *ulParmNum*

SplSetJob Parameter - cbBuf

cbBuf ([ULONG](#)) - input
Size, in bytes, of Buffer.

It must be greater than 0.

SplSetJob Parameter - ulParmNum

ulParmNum ([ULONG](#)) - input
Parameter number.

Specifies either that the entire [PRJINFO3](#) structure is to be modified, or that only one specific parameter is to be modified.

If *ulParmNum* is 0, *pBuf* must contain a complete [PRJINFO3](#) structure. Otherwise, *pBuf* must contain a new valid value for the parameter to be modified. The following are the possible values for this parameter:

Parameter	Value
<i>pszNotifyName</i>	PRJ_NOTIFYNAME_PARMNUM (3)
<i>pszDataType</i>	PRJ_DATATYPE_PARMNUM (4)
<i>pszParms</i>	PRJ_PARS_PARMNUM (5)
<i>uPosition</i>	PRJ_POSITION_PARMNUM (6)
<i>pszComment</i>	PRJ_COMMENT_PARMNUM (11)
<i>pszDocument</i>	PRJ_DOCUMENT_PARMNUM (12)
<i>pszStatus</i>	PRJ_STATUSCOMMENT_PARMNUM (13)
<i>uPriority</i>	PRJ_PRIORITY_PARMNUM (14)
<i>pszQProcParms</i>	PRJ_PROCPARMS_PARMNUM (16)
<i>pDriverData</i>	PRJ_DRIVERDATA_PARMNUM (18)

uPosition must be given the appropriate value, as follows:

Value	Change
0	No change
1	Move to first place
>1	Move to this position, or if the specified value is greater than the number of jobs in the queue, move to the end of the queue.

SplSetJob Return Value - rc

rc ([SPLERR](#)) - returns
Return code.

NO_ERROR (0)
No errors occurred.

ERROR_ACCESS_DENIED (5)
Access is denied.

ERROR_NOT_SUPPORTED (50)
This request is not supported by the network.

ERROR_BAD_NETPATH (53)
The network path cannot be located.

ERROR_INVALID_PARAMETER (87)
An invalid parameter is specified.

ERROR_INVALID_LEVEL (124)
The level parameter is invalid.

NERR_NetNotStarted (2102)
The network program is not started.

NERR_BufTooSmall (2123)
The API return buffer is too small.

NERR_JobNotFound (2151)
The print job does not exist.

NERR_SpoolerNotLoaded (2161)
The spooler is not running.

NERR_JobInvalidState (2164)
This operation cannot be performed on the print job in its current state.

NERR_SpoolNoMemory (2165)
A spooler memory allocation failure occurred.

NERR_DriverNotFound (2166)
The device driver does not exist.

NERR_ProcNotFound (2168)
The queue processor is not installed.

NERR_InvalidComputer (2351)
The computer name is invalid.

SplSetJob - Parameters

pszComputerName (PSZ) - input
Name of computer where job is to be modified.

A NULL string specifies the local workstation.

pszQueueName (PSZ) - input
Queue Name.

ulJob (ULONG) - input
Job identification number.

ulLevel (ULONG) - input
Level of detail required.

This must be 3.

pBuf (PVOID) - input
Buffer.

If *ulParmNum* is 0, this parameter must contain a complete [PRJINFO3](#) structure. Otherwise, it must contain a valid new value for the parameter of the [PRJINFO3](#) structure. indicated in *ulParmNum*

cbBuf (ULONG) - input
Size, in bytes, of Buffer.

It must be greater than 0.

ulParmNum (ULONG) - input
Parameter number.

Specifies either that the entire [PRJINFO3](#) structure is to be modified, or that only one specific parameter is to be modified.

If *ulParmNum* is 0, *pBuf* must contain a complete [PRJINFO3](#) structure. Otherwise, *pBuf* must contain a new valid value for the parameter to be modified. The following are the possible values for this parameter:

Parameter	Value
<i>pszNotifyName</i>	PRJ_NOTIFYNAME_PARMNUM (3)
<i>pszDataType</i>	PRJ_DATATYPE_PARMNUM (4)
<i>pszParms</i>	PRJ_PARS_PARMNUM (5)
<i>uPosition</i>	PRJ_POSITION_PARMNUM (6)
<i>pszComment</i>	PRJ_COMMENT_PARMNUM (11)
<i>pszDocument</i>	PRJ_DOCUMENT_PARMNUM (12)
<i>pszStatus</i>	PRJ_STATUSCOMMENT_PARMNUM (13)
<i>uPriority</i>	PRJ_PRIORITY_PARMNUM (14)
<i>pszQProcParms</i>	PRJ_PROCPARMS_PARMNUM (16)
<i>pDriverData</i>	PRJ_DRIVERDATA_PARMNUM (18)

uPosition must be given the appropriate value, as follows:

Value	Change
0	No change
1	Move to first place
>1	Move to this position, or if the specified value is greater than the number of jobs in the queue, move to the end of the queue.

rc ([SPLERR](#)) - returns

Return code.

NO_ERROR (0)	No errors occurred.
ERROR_ACCESS_DENIED (5)	Access is denied.
ERROR_NOT_SUPPORTED (50)	This request is not supported by the network.
ERROR_BAD_NETPATH (53)	The network path cannot be located.
ERROR_INVALID_PARAMETER (87)	An invalid parameter is specified.
ERROR_INVALID_LEVEL (124)	The level parameter is invalid.
NERR_NetNotStarted (2102)	The network program is not started.
NERR_BufTooSmall (2123)	The API return buffer is too small.
NERR_JobNotFound (2151)	The print job does not exist.
NERR_SpoolerNotLoaded (2161)	The spooler is not running.
NERR_JobInvalidState (2164)	This operation cannot be performed on the print job in its current state.
NERR_SpoolNoMemory (2165)	A spooler memory allocation failure occurred.
NERR_DriverNotFound (2166)	The device driver does not exist.
NERR_ProcNotFound (2168)	The queue processor is not installed.
NERR_InvalidComputer (2351)	The computer name is invalid.

SplSetJob - Remarks

The job priority is changed, if necessary, to the priority of the next job after the new position. If the spooler is restarted, the order in which jobs are put on the queue depends on the priority and age of the job. This order may be different from the order following the SplSetJob call.

Users without administrator privilege can use SplSetJob only for jobs created when the same user name was logged on. They can move jobs backwards only, and cannot increase the job priority above the queue priority.

A job created locally has no associated user name, and any user can set information locally for the job. Only an administrator can set

information for a job on a remote server.

SplSetPort

SplSetPort - Syntax

Description:

This function sets the BIDI capabilities of a printer port.

This function is used by the print object or other applications to enable or disable BIDI communications with a printer. If the port driver is capable of BIDI communications, SplSetPort can override the port driver and disable BIDI with the printer. This is useful in case there are problems with the BIDI components.

```
#define INCL_SPL
#define INCL_SPLBIDI
#include <os2.h>

PSZ      pszComputerName; /* Name of the computer connected to the port. */
PSZ      pszPortName;    /* Name of the port to set. */
ULONG    ulLevel;        /* Level of information to set. */
PVOID    pBuf;           /* Buffer containing new port setting. */
ULONG    cbBuf;          /* Length of buffer pointed to by pBuf, in bytes. */
ULONG    ulParmNum;      /* Parameter number used to change port settings. */
ULONG    rc;             /* Return codes. */

rc = SplSetPort(pszComputerName, pszPortName,
               ulLevel, pBuf, cbBuf, ulParmNum);
```

SplSetPort Parameter - pszComputerName

pszComputerName (**PSZ**) - input
Name of the computer connected to the port.

This value can be NULL for a local machine.

SplSetPort Parameter - pszPortName

pszPortName (**PSZ**) - input
Name of the port to set.

SplSetPort Parameter - ulLevel

ulLevel (**ULONG**) - input
Level of information to set.

This must be 2.

SplSetPort Parameter - pBuf

pBuf (**PVOID**) - input

Buffer containing new port setting.

SplSetPort Parameter - cbBuf

cbBuf (**ULONG**) - input
Length of buffer pointed to by *pBuf*, in bytes.

SplSetPort Parameter - ulParmNum

ulParmNum (**ULONG**) - input
Parameter number used to change port settings.

Parameter number must be one of the following:

Value	Description								
1	PRPO_PORT_DRIVER Port driver. This will be the new port driver for the printer port.								
2	PRPO_PROTOCOL_CNV Protocol converter. This will override the values returned by BIDI_Q_PORT. The spooler will use this protocol converter when using this port in BIDI mode.								
3	PRPO_MODE BIDI mode of the port. The ULONG value pointed to by <i>pBuf</i> must be one of the following values: <table><tr><th>Value</th><th>Description</th></tr><tr><td>1</td><td>PRPORT_AUTODETECT Auto-detect mode. The spooler will use the results of BIDI_Q_PORT to decide if BIDI should be enabled and which protocol converter to use. This is the default.</td></tr><tr><td>2</td><td>PRPORT_DISABLE_BIDI BIDI disabled. The spooler will not use the printer in BIDI mode. This overrides the port driver.</td></tr><tr><td>3</td><td>PRPORT_ENABLE_BIDI BIDI enabled. This is set only if an application knows a printer is capable of using a protocol converter, but the port driver does not know which converter to use. The application must also supply the protocol converter name when setting a port to this mode.</td></tr></table>	Value	Description	1	PRPORT_AUTODETECT Auto-detect mode. The spooler will use the results of BIDI_Q_PORT to decide if BIDI should be enabled and which protocol converter to use. This is the default.	2	PRPORT_DISABLE_BIDI BIDI disabled. The spooler will not use the printer in BIDI mode. This overrides the port driver.	3	PRPORT_ENABLE_BIDI BIDI enabled. This is set only if an application knows a printer is capable of using a protocol converter, but the port driver does not know which converter to use. The application must also supply the protocol converter name when setting a port to this mode.
Value	Description								
1	PRPORT_AUTODETECT Auto-detect mode. The spooler will use the results of BIDI_Q_PORT to decide if BIDI should be enabled and which protocol converter to use. This is the default.								
2	PRPORT_DISABLE_BIDI BIDI disabled. The spooler will not use the printer in BIDI mode. This overrides the port driver.								
3	PRPORT_ENABLE_BIDI BIDI enabled. This is set only if an application knows a printer is capable of using a protocol converter, but the port driver does not know which converter to use. The application must also supply the protocol converter name when setting a port to this mode.								
4	PRPO_PRIORITY Priority. Currently not supported.								

SplSetPort Return Value - rc

rc (**ULONG**) - returns
Return codes.

0	Success
ERROR_INVALID_PARAMETER(87)	An invalid parameter was specified; most likely an invalid <i>pBuf</i> value or an invalid <i>ulParmNum</i> value.
ERROR_NOT_SUPPORTED(50)	Command not supported on <i>pszComputerName</i> .
NERR_DestNotFound(2152)	The port name does not exist.

SplSetPort - Parameters

pszComputerName (PSZ) - input

Name of the computer connected to the port.

This value can be NULL for a local machine.

pszPortName (PSZ) - input

Name of the port to set.

ulLevel (ULONG) - input

Level of information to set.

This must be 2.

pBuf (PVOID) - input

Buffer containing new port setting.

cbBuf (ULONG) - input

Length of buffer pointed to by *pBuf*, in bytes.

ulParmNum (ULONG) - input

Parameter number used to change port settings.

Parameter number must be one of the following:

Value	Description
1	PRPO_PORT_DRIVER Port driver. This will be the new port driver for the printer port.
2	PRPO_PROTOCOL_CNV Protocol converter. This will override the values returned by BIDI_Q_PORT. The spooler will use this protocol converter when using this port in BIDI mode.
3	PRPO_MODE BIDI mode of the port. The ULONG value pointed to by <i>pBuf</i> must be one of the following values:
Value	Description
1	PRPORT_AUTODETECT Auto-detect mode. The spooler will use the results of BIDI_Q_PORT to decide if BIDI should be enabled and which protocol converter to use. This is the default.
2	PRPORT_DISABLE_BIDI BIDI disabled. The spooler will not use the printer in BIDI mode. This overrides the port driver.
3	PRPORT_ENABLE_BIDI BIDI enabled. This is set only if an application knows a printer is

capable of using a protocol converter, but the port driver does not know which converter to use. The application must also supply the protocol converter name when setting a port to this mode.

4	PRPO_PRIORITY Priority. Currently not supported.
rc (ULONG) - returns Return codes.	
0	Success
ERROR_INVALID_PARAMETER(87)	An invalid parameter was specified; most likely an invalid <i>pBuf</i> value or an invalid <i>ulParmNum</i> value.
ERROR_NOT_SUPPORTED(50)	Command not supported on <i>pszComputerName</i> .
NERR_DestNotFound(2152)	The port name does not exist.

SplSetPort - Remarks

None.

SplSetQueue

SplSetQueue - Syntax

This function modifies the configuration of a print queue.

```
#define INCL_SPL /* Or use INCL_PM, */
#include <os2.h>

PSZ      pszComputerName; /* Name of computer where queue is to be modified. */
```

```
PSZ      pszQueueName;      /* Queue name. */
ULONG    ulLevel;           /* Level of detail required. */
PVOID    pBuf;              /* Buffer. */
ULONG    cbBuf;             /* Size, in bytes, of Buffer. */
ULONG    ulParmNum;         /* Parameter number. */
SPLERR    rc;               /* Return code. */
```

```
rc = SplSetQueue(pszComputerName, pszQueueName,
                 ulLevel, pBuf, cbBuf, ulParmNum);
```

SplSetQueue Parameter - pszComputerName

pszComputerName ([PSZ](#)) - input

Name of computer where queue is to be modified.

A NULL string specifies the local workstation.

SplSetQueue Parameter - pszQueueName

pszQueueName ([PSZ](#)) - input

Queue name.

SplSetQueue Parameter - ulLevel

ulLevel ([ULONG](#)) - input

Level of detail required.

This must be 3 or 6.

SplSetQueue Parameter - pBuf

pBuf ([PVOID](#)) - input

Buffer.

If *ulParmNum* is 0, this parameter must contain a complete [PRQINFO3](#) or [PRQINFO6](#) structure. Otherwise, it must contain a valid new value for the parameter of the [PRQINFO3](#) or the [PRQINFO6](#) structure indicated in *ulParmNum*.

SplSetQueue Parameter - cbBuf

cbBuf (**ULONG**) - input
Size, in bytes, of Buffer.

SplSetQueue Parameter - ulParmNum

ulParmNum (**ULONG**) - input
Parameter number.

Specifies either that the entire **PRQINFO3** or **PRQINFO6** structure is to be modified, or that only one specific parameter is to be modified.

Possible values for this parameter are as follows:

Parameter	Constant (Value)
<i>uPriority</i>	PRQ_PRIORITY_PARMNUM (2)
<i>uStartTime</i>	PRQ_STARTTIME_PARMNUM (3)
<i>uUntilTime</i>	PRQ_UNTILTIME_PARMNUM (4)
<i>pszSepFile</i>	PRQ_SEPARATOR_PARMNUM (5)
<i>pszPrProc</i>	PRQ_PROCESSOR_PARMNUM (6)
<i>pszParms</i>	PRQ_PARS_PARMNUM (8)
<i>pszComment</i>	PRQ_COMMENT_PARMNUM (9)
<i>fsType</i>	PRQ_TYPE_PARMNUM (10)
<i>pszPrinters</i>	PRQ_PRINTERS_PARMNUM (12)
<i>pszDriverName</i>	PRQ_DRIVERNAME_PARMNUM (13)
<i>pDriverData</i>	PRQ_DRIVERDATA_PARMNUM (14)
<i>pszRemoteComputerName</i>	PRQ_REMOTE_COMPUTER_PARMNUM (15)
<i>pszRemoteQueueName</i>	PRQ_REMOTE_QUEUE_PARMNUM (16)

SplSetQueue Return Value - rc

rc (**SPLERR**) - returns
Return code.

NO_ERROR (0)	No errors occurred.
ERROR_ACCESS_DENIED (5)	Access is denied.
ERROR_NOT_SUPPORTED (50)	This request is not supported by the network.
ERROR_BAD_NETPATH (53)	The network path cannot be located.
ERROR_INVALID_PARAMETER (87)	An invalid parameter is specified.
ERROR_INVALID_LEVEL (124)	The level parameter is invalid.
NERR_NetNotStarted (2102)	The network program is not installed.
NERR_RedirectedPath (2117)	The operation is invalid on a redirected resource.
NERR_BufTooSmall (2123)	The API return buffer is too small.
NERR_QNotFound (2150)	The printer queue does not exist.
NERR_DestNotFound (2152)	

The printer destination cannot be found.
NERR_DestNoRoom (2157)
The maximum number of printer destinations has been reached.
NERR_DestInvalidState (2162)
This operation cannot be performed on the print destination.
NERR_SpoolNoMemory (2165)
A spooler memory allocation failure occurred.
NERR_DriverNotFound (2166)
The device driver does not exist.
NERR_DataTypeInvalid (2167)
The datatype is not supported by the processor.
NERR_ProcNotFound (2168)
The queue processor is not installed.
NERR_BadDev (2341)
The requested device is invalid.
NERR_CommDevInUse (2343)
The requested device is invalid.
NERR_InvalidComputer (2351)
The computer name is invalid.

SplSetQueue - Parameters

pszComputerName (PSZ) - input
Name of computer where queue is to be modified.

A NULL string specifies the local workstation.

pszQueueName (PSZ) - input
Queue name.

ulLevel (ULONG) - input
Level of detail required.

This must be 3 or 6.

pBuf (PVOID) - input
Buffer.

If *ulParmNum* is 0, this parameter must contain a complete **PRQINFO3** or **PRQINFO6** structure. Otherwise, it must contain a valid new value for the parameter of the **PRQINFO3** or the **PRQINFO6** structure indicated in *ulParmNum*.

cbBuf (ULONG) - input
Size, in bytes, of Buffer.

ulParmNum (ULONG) - input
Parameter number.

Specifies either that the entire **PRQINFO3** or **PRQINFO6** structure is to be modified, or that only one specific parameter is to be modified.

Possible values for this parameter are as follows:

Parameter	Constant (Value)
<i>uPriority</i>	PRQ_PRIORITY_PARMNUM (2)
<i>uStartTime</i>	PRQ_STARTTIME_PARMNUM (3)
<i>uUntilTime</i>	PRQ_UNTILTIME_PARMNUM (4)
<i>pszSepFile</i>	PRQ_SEPARATOR_PARMNUM (5)
<i>pszPrProc</i>	PRQ_PROCESSOR_PARMNUM (6)
<i>pszParams</i>	PRQ_PARAMS_PARMNUM (8)
<i>pszComment</i>	PRQ_COMMENT_PARMNUM (9)
<i>fsType</i>	PRQ_TYPE_PARMNUM (10)
<i>pszPrinters</i>	PRQ_PRINTERS_PARMNUM (12)
<i>pszDriverName</i>	PRQ_DRIVERNAME_PARMNUM (13)
<i>pDriverData</i>	PRQ_DRIVERDATA_PARMNUM (14)

pszRemoteComputerName
pszRemoteQueueName

PRQ_REMOTE_COMPUTER_PARMNUM (15)
PRQ_REMOTE_QUEUE_PARMNUM (16)

rc ([SPLERR](#)) - returns
Return code.

NO_ERROR (0)
No errors occurred.

ERROR_ACCESS_DENIED (5)
Access is denied.

ERROR_NOT_SUPPORTED (50)
This request is not supported by the network.

ERROR_BAD_NETPATH (53)
The network path cannot be located.

ERROR_INVALID_PARAMETER (87)
An invalid parameter is specified.

ERROR_INVALID_LEVEL (124)
The level parameter is invalid.

NERR_NetNotStarted (2102)
The network program is not installed.

NERR_RedirectedPath (2117)
The operation is invalid on a redirected resource.

NERR_BufTooSmall (2123)
The API return buffer is too small.

NERR_QNotFound (2150)
The printer queue does not exist.

NERR_DestNotFound (2152)
The printer destination cannot be found.

NERR_DestNoRoom (2157)
The maximum number of printer destinations has been reached.

NERR_DestInvalidState (2162)
This operation cannot be performed on the print destination.

NERR_SpoolNoMemory (2165)
A spooler memory allocation failure occurred.

NERR_DriverNotFound (2166)
The device driver does not exist.

NERR_DataTypeInvalid (2167)
The datatype is not supported by the processor.

NERR_ProcNotFound (2168)
The queue processor is not installed.

NERR_BadDev (2341)
The requested device is invalid.

NERR_CommDevInUse (2343)
The requested device is invalid.

NERR_InvalidComputer (2351)
The computer name is invalid.

SplSetQueue - Remarks

If the *uPriority* field in [PRQINFO3](#) or [PRQINFO6](#) is set to PRQ_NO_PRIORITY, the queue priority is not changed.

SplSetQueue - Example Code

This sample code prompts the user to enter a parameter number and a value at the prompt. This value is then put into a buffer for use by the function.

```
#define INCL_SPL
#define INCL_SPLDOSPRINT
#define INCL_SPLERRORS

#include <os2.h>
#include <stdio.h>      /* for printf function */
#include <stdlib.h>     /* for atoi function  */
#include <string.h>     /* for strlen function */

INT main (argc, argv)
    INT argc;
    CHAR *argv[];
{
    CHAR    bufValue[2] = {0};
    CHAR    bufInput[128]= {0};
    ULONG   splerr ;
    ULONG   cbBuf ;
    ULONG   ulParmNum ;
    USHORT  usParm ;
    PSZ     pszComputerName ;
    PSZ     pszQueueName ;
    PVOID    pBuf;

    if (argc != 2)
    {
        printf("Syntax:  setgryq QueueName \n");
        DosExit( EXIT_PROCESS , 0 ) ;
    }

    /* This function will be for the local workstation.
    pszComputerName = (PSZ)NULL ;

    /* Get the parameter from the command line.
    pszQueueName = argv[1];

    /* Prompt the user for the parameter and values, and put them in buffers. */
    printf("Enter Parameter number to be modified\n");
    gets(&bufValue[0]);
    printf("Enter new parameter value \n");
    gets(&bufInput[0]);

    /* Convert the ParmNum to a ULONG.
    ulParmNum = atoi(&bufValue[0]);
    switch (ulParmNum){
        case 2:
        case 3:
        case 4:
        case 10:
            /* Determine the size of the buffer needed.
            cbBuf = sizeof(PUSHORT);

            /* Convert the buffer input to a USHORT.
            usParm =(USHORT)atoi(&bufInput[0]);

            /* Set the pBuf pointer to point to the value obtained.
            pBuf = &usParm;
            break;
        case 5:
        case 6:
        case 8:
        case 9:
        case 12:
        case 13:
            /* Determine the size of the buffer needed.
            cbBuf = strlen(&bufInput[0])+1;
```

```

        /* Set the pBuf pointer to point to the value obtained from input. */
        pBuf = (PSZ)&bufInput;
        break;
    case 14:
        printf("For simplicity this is not implemented.");
        break;
    default:
        printf("Invalid number\n");
        DosExit( EXIT_PROCESS , 0 ) ;
        break;
}

/* Make the call with all the proper parameters. */
splerr = SplSetQueue(pszComputerName, pszQueueName, 3L,
                    pBuf, cbBuf, ulParmNum) ;

/* Print the resultant error code, and the parameters entered. */
printf("SplSetQueue Error= %ld, Parameter= %d, cbBuf= %ld,
        ulParmNum= %ld\n",
        splerr, usParm, cbBuf, ulParmNum);
DosExit( EXIT_PROCESS , 0 ) ;
return (splerr);
}

SplUnRegister

SplUnRegister - Syntax

Description:

This function allows applications to unregister for notification of events about printers. This function should be used when an application no longer wants certain alerts, in order to limit the network traffic.

```

#define INCL_SPL
#define INCL_SPLBIDI
#include <os2.h>

PSZ      pszComputerName; /* Printer server name to unregister for alert notification. */
PSZ      pszName;         /* Case-sensitive name of printer port to unregister for alerts. */
ULONG    ulHandle;        /* Spooler alert handle previously allocated by SplRegister. */

```

```

ULONG    ulCategory;        /* Category of alert to unregister. */
ULONG    ulType;            /* Type of alert to unregister for the given category. */
ULONG    rc;                /* Return codes. */

rc = SplUnRegister(pszComputerName, pszName,
    ulHandle, ulCategory, ulType);

```

SplUnRegister Parameter - pszComputerName

pszComputerName ([PSZ](#)) - input
 Printer server name to unregister for alert notification.

This value is NULL for local printer ports.

SplUnRegister Parameter - pszName

pszName ([PSZ](#)) - input
 Case-sensitive name of printer port to unregister for alerts.

This value can be a virtual port name.

SplUnRegister Parameter - ulHandle

ulHandle ([ULONG](#)) - input
 Spooler alert handle previously allocated by SplRegister.

SplUnRegister Parameter - ulCategory

ulCategory ([ULONG](#)) - input
 Category of alert to unregister.

This value can be the core alert category or an extended alert category as defined below:

PRTALERT_CATEGORY_ALL - 0x00000000

Unregister for all alerts for the given alert handle. This will remove registration for all printer ports (even remote ones) for the alert handle.

PRTALERT_CATEGORY_ALL_CORE - 0x00000002

Unregister for all core alerts for the port.

PRTALERT_CATEGORY_ALL_EXT - 0x00000003

Unregister for all extended alerts for the port.

PRTALERT_CATEGORY_CORE - 0x00000001

Core alert category. This will remove registration for only those core alerts whose bits are set in *ulType* for the port.

PRTALERT_CATEGORY_EXT_MAX - 0x0000DFFF

End of the extended alert categories.

PRTALERT_CATEGORY_EXTENDED - 0x0000D000

Beginning of the extended alert categories. Protocol converters should limit the category range to between 0x0000D000 and 0x0000DFFF.

If the protocol converter does not support the given category, ERROR_INVALID_CATEGORY(117) is returned.

SplUnRegister Parameter - ulType

ulType (ULONG) - input

Type of alert to unregister for the given category.

If the category is PRTALERT_CATEGORY_CORE, then this is a bit-field that defines the core alerts to unregister.

If the category is **not** PRTALERT_CATEGORY_ALL, PRTALERT_CATEGORY_CORE, PRTALERT_CATEGORY_ALL_CORE, or PRTALERT_CATEGORY_ALL_EXT, this is a value that defines the specific extended alert to unregister.

SplUnRegister Return Value - rc

rc (ULONG) - returns

Return codes.

0 Success

ERROR_FILE_NOT_FOUND(2)
pszName is not a valid port name.

ERROR_INVALID_HANDLE(6)
The value *ulHandle* is not a valid spooler alert handle.

ERROR_INVALID_PARAMETER(87)
An invalid buffer given.

ERROR_NOT_SUPPORTED(50)
The spooler on the given print server cannot support alert notification.

PMERR_SPL_NOT_REGISTERED(0x4042)
The alert handle *ulHandle* is not currently registered for any alerts specified by *ulCategory* and *ulType*.

PMERR_SPL_SPOOLER_NOT_INSTALLED(0x4009)
The spooler is not enabled.

SplUnRegister - Parameters

pszComputerName (PSZ) - input
Printer server name to unregister for alert notification.

This value is NULL for local printer ports.

pszName (PSZ) - input
Case-sensitive name of printer port to unregister for alerts.

This value can be a virtual port name.

ulHandle (ULONG) - input
Spooler alert handle previously allocated by SplRegister.

ulCategory (ULONG) - input
Category of alert to unregister.

This value can be the core alert category or an extended alert category as defined below:

PRTALERT_CATEGORY_ALL - 0x00000000
Unregister for all alerts for the given alert handle. This will remove registration for all printer ports (even remote ones) for the alert handle.

PRTALERT_CATEGORY_ALL_CORE - 0x00000002
Unregister for all core alerts for the port.

PRTALERT_CATEGORY_ALL_EXT - 0x00000003
Unregister for all extended alerts for the port.

PRTALERT_CATEGORY_CORE - 0x00000001
Core alert category. This will remove registration for only those core alerts whose bits are set in *ulType* for the port.

PRTALERT_CATEGORY_EXT_MAX - 0x0000DFFF
End of the extended alert categories.

PRTALERT_CATEGORY_EXTENDED - 0x0000D000
Beginning of the extended alert categories. Protocol converters should limit the category range to between 0x0000D000 and 0x0000DFFF.

If the protocol converter does not support the given category, ERROR_INVALID_CATEGORY(117) is returned.

ulType (ULONG) - input
Type of alert to unregister for the given category.

If the category is PRTALERT_CATEGORY_CORE, then this is a bit-field that defines the core alerts to unregister.

If the category is **not** PRTALERT_CATEGORY_ALL, PRTALERT_CATEGORY_CORE, PRTALERT_CATEGORY_ALL_CORE, or PRTALERT_CATEGORY_ALL_EXT, this is a value that defines the specific extended alert to unregister.

rc (ULONG) - returns
Return codes.

0 Success

ERROR_FILE_NOT_FOUND(2)
pszName is not a valid port name.

ERROR_INVALID_HANDLE(6)
The value *ulHandle* is not a valid spooler alert handle.

ERROR_INVALID_PARAMETER(87)
An invalid buffer given.

ERROR_NOT_SUPPORTED(50)
The spooler on the given print server cannot support alert notification.

PMERR_SPL_NOT_REGISTERED(0x4042)
The alert handle *ulHandle* is not currently registered for any alerts specified by *ulCategory* and *ulType*.

PMERR_SPL_SPOOLER_NOT_INSTALLED(0x4009)
The spooler is not enabled.

SplUnRegister - Remarks

Registration is **not** maintained across reboots.

Window Functions

The PM user interface is based on *windows*-areas of the screen through which applications interact with the user. This section contains an alphabetical list of the functions which are available to the application for using and controlling windows.

WinAddAtom

WinAddAtom - Syntax

This function adds an atom to an atom table.

```
#define INCL_WINATOM /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HATOMTBL    hatomtblAtomTbl; /* Atom-table handle. */
PSZ         AtomName;        /* Atom name. */
ATOM        atom;             /* Atom value. */

atom = WinAddAtom(hatomtblAtomTbl, AtomName);
```

WinAddAtom Parameter - hatomtblAtomTbl

hatomtblAtomTbl ([HATOMTBL](#)) - input
Atom-table handle.

This is the handle returned by a previous call to [WinCreateAtomTable](#) or [WinQuerySystemAtomTable](#).

WinAddAtom Parameter - AtomName

AtomName ([PSZ](#)) - input
Atom name.

This is a character string to be added to the table.

If the string begins with an "#" character, the five ASCII digits that follow are converted into an integer atom. If this integer is a valid integer atom, this function returns that atom, without modifying the atom table.

If the string begins with an "!" character, the next four bytes are interpreted as an atom. If it is an integer atom, that atom is returned. If it is not an integer atom and it is a valid atom for the given atom table (that is, it has an atom name and use count associated with it) the use count of that atom is incremented by one and the atom is returned. Otherwise 0 is returned.

If the high order word of the string is minus one, the low order word is an atom. If it is an integer atom, that atom is returned. If it is not

an integer atom and it is a valid atom for the given atom table (that is, it has an atom name and use count associated with it) the use count of that atom is incremented by one and the atom is returned. Otherwise 0 is returned.

WinAddAtom Return Value - atom

atom ([ATOM](#)) - returns
Atom value.

Atom

The atom associated with the passed string

0

Invalid atom-table handle or invalid atom name specified.

WinAddAtom - Parameters

hatomtblAtomTbl ([HATOMTBL](#)) - input
Atom-table handle.

This is the handle returned by a previous call to [WinCreateAtomTable](#) or [WinQuerySystemAtomTable](#).

AtomName ([PSZ](#)) - input
Atom name.

This is a character string to be added to the table.

If the string begins with an "#" character, the five ASCII digits that follow are converted into an integer atom. If this integer is a valid integer atom, this function returns that atom, without modifying the atom table.

If the string begins with an "!" character, the next four bytes are interpreted as an atom. If it is an integer atom, that atom is returned. If it is not an integer atom and it is a valid atom for the given atom table (that is, it has an atom name and use count associated with it) the use count of that atom is incremented by one and the atom is returned. Otherwise 0 is returned.

If the high order word of the string is minus one, the low order word is an atom. If it is an integer atom, that atom is returned. If it is not an integer atom and it is a valid atom for the given atom table (that is, it has an atom name and use count associated with it) the use count of that atom is incremented by one and the atom is returned. Otherwise 0 is returned.

atom ([ATOM](#)) - returns
Atom value.

Atom

The atom associated with the passed string

0

Invalid atom-table handle or invalid atom name specified.

WinAddAtom - Remarks

If the atom name represents an integer atom, this function returns the atom represented by the passed atom name.

If the atom name does not represent an integer atom and if the atom name already exists in the atom table, this function increments the use count of that atom by one. Otherwise, the atom is added to the table and its use count is set to one. In either case this function returns the atom represented by the passed atom name.

WinAddAtom - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HATOMTBL (0x1013)

An invalid atom-table handle was specified.

PMERR_INVALID_INTEGER_ATOM (0x1016)

The specified atom is not a valid integer atom.

PMERR_INVALID_ATOM_NAME (0x1015)

An invalid atom name string was passed.

PMERR_ATOM_NAME_NOT_FOUND (0x1017)

The specified atom name is not in the atom table.

WinAddAtom - Example Code

This example creates an Atom Table and then adds the atom "newatom" to the new table; it then checks the count for this new atom to verify that it is 1.

```
#define INCL_WINATOM          /* Window Atom Functions          */
#include <os2.h>

ATOM  atom;                  /* new atom value          */
HATOMTBL  hatomtblAtomTbl; /* atom-table handle      */
char  pszAtomName[10]; /* atom name              */
ULONG  ulInitial = 0; /* initial atom table size (use default) */
ULONG  ulBuckets = 0; /* size of hash table (use default) */
ULONG  ulCount; /* atom usage count      */
BOOL  atomCount1 = FALSE; /* indicates atom count != 1 */

/* create atom table of default size */
hatomtblAtomTbl = WinCreateAtomTable(ulInitial, ulBuckets);

/* define name for new atom and add to table */
strcpy(pszAtomName, "newatom");
atom = WinAddAtom(hatomtblAtomTbl, pszAtomName);

ulCount = WinQueryAtomUsage(hatomtblAtomTbl, atom);

/* verify that usage count is 1 */
if (ulCount == 1)
```

```
atomCount1 = TRUE;
```

[Related Functions](#)

[Glossary](#)

WinAddSwitchEntry

WinAddSwitchEntry - Syntax

This function adds an entry to the Window List. This is a list of running programs that is displayed to the user by the operating system.

```
#define INCL_WINSWITCHLIST /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

SWCNTRL    swctlSwitchData; /* Switch data. */
HSWITCH    hswitchSwitch; /* Handle to the newly created Window List entry. */

hswitchSwitch = WinAddSwitchEntry(swctlSwitchData);
```

WinAddSwitchEntry Parameter - swctlSwitchData

swctlSwitchData ([SWCNTRL](#)) - input
Switch data.

Contains information about the newly created Window List entry.

If the *szSwtitle* field of the [SWCNTRL](#) structure is 0, the system uses the name under which the application is started. This only applies for the first call to this function since the program started. Otherwise, a NULL entry name is invalid.

The title is truncated, if necessary, to 60 characters.

If the *hprog* field of the [SWCNTRL](#) structure is NULLHANDLE, the value used by the system when the program was loaded (if it has been loaded) is substituted.

If the *idProcess* field of the [SWCCTRL](#) structure is 0, the current process ID is used.

If the *idSession* field of the [SWCCTRL](#) structure is 0, the current session ID is used.

If the *hwndIcon* field of the [SWCCTRL](#) structure is NULLHANDLE, the system supplies a default icon.

WinAddSwitchEntry Return Value - hswitchSwitch

hswitchSwitch ([HSWITCH](#)) - returns

Handle to the newly created Window List entry.

There is a system limit to the number of Window List entries. However, this is a large number (several hundred) and is unlikely to be reached in practice because other system limits, such as memory size, restrict the number before this limit is reached.

NULLHANDLE

Error occurred

Other

Handle to the newly created Window List entry.

WinAddSwitchEntry - Parameters

swctlSwitchData ([SWCCTRL](#)) - input

Switch data.

Contains information about the newly created Window List entry.

If the *szSwtitle* field of the [SWCCTRL](#) structure is 0, the system uses the name under which the application is started. This only applies for the first call to this function since the program started. Otherwise, a NULL entry name is invalid.

The title is truncated, if necessary, to 60 characters.

If the *hprog* field of the [SWCCTRL](#) structure is NULLHANDLE, the value used by the system when the program was loaded (if it has been loaded) is substituted.

If the *idProcess* field of the [SWCCTRL](#) structure is 0, the current process ID is used.

If the *idSession* field of the [SWCCTRL](#) structure is 0, the current session ID is used.

If the *hwndIcon* field of the [SWCCTRL](#) structure is NULLHANDLE, the system supplies a default icon.

hswitchSwitch ([HSWITCH](#)) - returns

Handle to the newly created Window List entry.

There is a system limit to the number of Window List entries. However, this is a large number (several hundred) and is unlikely to be reached in practice because other system limits, such as memory size, restrict the number before this limit is reached.

NULLHANDLE

Error occurred

Other

Handle to the newly created Window List entry.

WinAddSwitchEntry - Remarks

Neither this function nor the [WinRemoveSwitchEntry](#) function are required if the main window is created with the frame creation flags FCF_TASKLIST or FCF_STANDARD, because these flags automatically update the Window List when the main window is created or destroyed.

WinAddSwitchEntry - Errors

Possible returns from [WinGetLastError](#)

PMERR_NO_SPACE (0x1201)

The limit on the number of Window List entries has been reached with WinAddSwitchEntry.

PMERR_INVALID_SESSION_ID (0x120B)

The specified session identifier is invalid. Either zero (for the application's own session) or a valid identifier must be specified.

PMERR_INVALID_WINDOW (0x1206)

The window specified with a Window List call is not a valid frame window.

WinAddSwitchEntry - Example Code

This example calls WinQueryWindowProcess to get the current process identifier (needed for the SWCNTRL structure). It then sets up the swctl structure and calls WinAddSwitchEntry to add the name of the program to the task list. The returned handle can be used in subsequent calls to WinChangeSwitchEntry if the title needs to be changed. The variables swctl, hswitch, and pid should be global if the application will be calling the WinChangeSwitchEntry function to avoid having to set up the structure again.

```
#define INCL_WINSWITCHLIST          /* Window Task Switch functions */
#include <os2.h>

SWCNTRL swctl;                     /* Switch control data */
HSWITCH hswitch;                   /* Switch handle */
PID pid;                           /* Process id */
HWND hwndFrame;                   /* Frame handle */

WinQueryWindowProcess(hwndFrame, &pid, NULL);

swctl.hwnd = hwndFrame;             /* Window handle */
swctl.hwndIcon = NULLHANDLE;       /* Icon handle */
swctl.hprog = NULLHANDLE;          /* Program handle */
swctl.idProcess = pid;              /* Process identifier */
swctl.idSession = 0;               /* Session identifier */
```

```

swctl.uchVisibility = SWL_VISIBLE; /* Visibility          */
swctl.fbJump = SWL_JUMPABLE;      /* Jump indicator  */
swctl.szSwttitle[0] = 0;          /* Program name    */
swctl.bProgType = PROG_DEFAULT;   /* Program type    */

hswitch = WinAddSwitchEntry(&swctl);

```

WinAlarm

WinAlarm - Syntax

This function generates an audible alarm.

```

#define INCL_WINDIALOGS /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HWND    hwndDeskTop; /* Desktop-window handle. */
ULONG   flStyle;     /* Alarm style. */
BOOL     rc;          /* Alarm-generated indicator. */

rc = WinAlarm(hwndDeskTop, flStyle);

```

WinAlarm Parameter - hwndDeskTop

hwndDeskTop (HWND) - input
Desktop-window handle.

HWND_DESKTOP	The desktop window
Other	Specified desktop window.

WinAlarm Parameter - flStyle

flStyle ([ULONG](#)) - input
Alarm style.

Used to signify different situations to the operator.

The duration and frequency of the alarms can be changed by the [WinSetSysValue](#) function. The alarm frequency is defined to be in the range 0x0025 through 0x7FFF. The alarm is not generated if system value SV_ALARM is set to FALSE. The alarms are dependent on the device capability. Different alarms are selected by use of these values:

- WA_WARNING
- WA_NOTE
- WA_ERROR

WinAlarm Return Value - rc

rc ([BOOL](#)) - returns
Alarm-generated indicator.

- | | |
|-------|----------------------|
| TRUE | Alarm generated |
| FALSE | Alarm not generated. |

WinAlarm - Parameters

hwndDesktop ([HWND](#)) - input
Desktop-window handle.

- | | |
|--------------|---------------------------|
| HWND_DESKTOP | The desktop window |
| Other | Specified desktop window. |

flStyle ([ULONG](#)) - input
Alarm style.

Used to signify different situations to the operator.

The duration and frequency of the alarms can be changed by the [WinSetSysValue](#) function. The alarm frequency is defined to be in the range 0x0025 through 0x7FFF. The alarm is not generated if system value SV_ALARM is set to FALSE. The alarms are dependent on the device capability. Different alarms are selected by use of these values:

- WA_WARNING
- WA_NOTE

WA_ERROR

rc ([BOOL](#)) - returns
Alarm-generated indicator.

TRUE	Alarm generated
FALSE	Alarm not generated.

WinAlarm - Remarks

Although this function is in the INCL_WINDIALOGS section, it is part of the common subset and is also included if INCL_COMMON is defined.

WinAlarm - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

PMERR_INVALID_PARM (0x1303)
A parameter to the function contained invalid data.

WinAlarm - Related Functions

WinAssociateHelpInstance

WinAssociateHelpInstance - Syntax

This function associates the specified instance of the Help Manager with the window chain of the specified application window.

```
#define INCL_WINHELP /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND     hwndHelpInstance; /* Handle of an instance of the Help Manager. */
HWND     hwndApp;          /* Handle of an application window. */
BOOL     rc;               /* Success indicator. */

rc = WinAssociateHelpInstance(hwndHelpInstance,
                              hwndApp);
```

WinAssociateHelpInstance Parameter - hwndHelpInstance

hwndHelpInstance ([HWND](#)) - input

Handle of an instance of the Help Manager.

This is the handle returned by the [WinCreateHelpInstance](#) call.

NULLHANDLE

Disassociates an instance of the Help Manager from a window chain when the instance has been destroyed.

Other

The handle of an instance of the Help Manager to be associated with the application window chain.

WinAssociateHelpInstance Parameter - hwndApp

hwndApp ([HWND](#)) - input
Handle of an application window.

The handle of the application window with which the instance of the Help Manager will be associated. The instance of the Help Manager is associated with the application window and any of its children or owned windows.

WinAssociateHelpInstance Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinAssociateHelpInstance - Parameters

hwndHelpInstance ([HWND](#)) - input
Handle of an instance of the Help Manager.

This is the handle returned by the [WinCreateHelpInstance](#) call.

NULLHANDLE	Disassociates an instance of the Help Manager from a window chain when the instance has been destroyed.
Other	The handle of an instance of the Help Manager to be associated with the application window chain.

hwndApp ([HWND](#)) - input
Handle of an application window.

The handle of the application window with which the instance of the Help Manager will be associated. The instance of the Help Manager is associated with the application window and any of its children or owned windows.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinAssociateHelpInstance - Remarks

In order to provide help, the application must associate an instance of the Help Manager with a chain of application windows. This association lets the Help Manager know which instance should provide the help function.

The Help Manager traces the window chain, starting from the window where help is requested. The application window in the chain with the

associated help instance will be the one with which the Help Manager communicates and next to which the help window is positioned, unless a [HM_SET_ACTIVE_WINDOW](#) message is sent to the Help Manager. If the [HM_SET_ACTIVE_WINDOW](#) message is sent to the Help Manager, the active window parameter is the window with which the Help Manager communicates. The Help Manager positions the help window next to the window specified as the relative window.

WinAssociateHelpInstance - Example Code

This example shows a typical main function for an application which uses help. Following creation of the main application window the Help Manager is initialized and associated with the window. The help table is defined in the application's resources. When the window is destroyed, terminating the application, the help instance is also destroyed.

```
#define INCL=_WIN
#include <os2.h>

#define IDHT_APPLICATION      100      /* id of HELP TABLE in resource file */

main( int argc, char *argv[], char *envp[] )
{
    HAB  hab = WinInitialize( 0 );
    HMQ  hmq = WinCreateMsgQueue( hab, 0 );
    HWND hwnd;
    HWND hwndClient;
    HWND hwndHelp;
    QMSG qmsg;
    ULONG flStyle;
    HELPINIT helpinit;

    /* Setup the help initialization structure */
    helpinit.cb = sizeof( HELPINIT );
    helpinit.ulReturnCode = 0L;
    helpinit.pszTutorialName = (PSZ)NULL;
    /* Help table in application resource */
    helpinit.phtHelpTable = (PHELPTABLE)MAKEULONG( IDHT_APPLICATION, 0xffff );
    helpinit.hmodHelpTableModule = NULLHANDLE;
    /* Default action bar and accelerators */
    helpinit.hmodAccelActionBarModule = NULLHANDLE;
    helpinit.idAccelTable = 0;
    helpinit.idActionBar = 0;
    helpinit.pszHelpWindowTitle = "APPNAME HELP";
    helpinit.fShowPanelId = CMIC_SHOW_PANEL_ID;
```

```

helpinit.pszHelpLibraryName = "APPNAME.HLP";

/* Register the class */
if( WinRegisterClass( ... ) )
{
    /* create the main window */
    flStyle = FCF_STANDARD;
    hwnd = WinCreateStdWindow( ... );

    if( hwnd )
    {
        /* Create and associate the help instance */
        hwndHelp = WinCreateHelpInstance( hab, &helpinit );

        if( hwndHelp && WinAssociateHelpInstance( hwndHelp, hwnd ) )
        {
            /* Process messages */
            while( WinGetMsg( hab, &qmsg, NULLHANDLE, 0, 0 ) )
            {
                WinDispatchMsg( hab, &qmsg );
            } /* endwhile */
        }

        /* Remove help instance - note: add */
        /*      WinAssociateHelpInstance( NULLHANDLE, hwnd ); */
        /* to WM_DESTROY processing to remove the association. */
        WinDestroyHelpInstance( hwndHelp );
    }
}

/* finish the cleanup and exit */
WinDestroyMsgQueue( hmq );
WinTerminate( hab );
}

WinBeginEnumWindows

WinBeginEnumWindows - Syntax

This function begins the enumeration process for all of the immediate child windows of a specified window.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
```

```
#include <os2.h>

HWND    hwnd;          /* Handle of the window whose child windows are to be enumerated. */
HENUM    henumHenum;    /* Enumeration handle. */

henumHenum = WinBeginEnumWindows(hwnd);
```

WinBeginEnumWindows Parameter - hwnd

hwnd ([HWND](#)) - input

Handle of the window whose child windows are to be enumerated.

HWND_DESKTOP

Enumerate all main windows

HWND_OBJECT

Enumerate all object windows

Other

Enumerate all immediate children of the specified window.

WinBeginEnumWindows Return Value - henumHenum

henumHenum ([HENUM](#)) - returns

Enumeration handle.

This is used in subsequent calls to the [WinGetNextWindow](#) function to return the immediate child-window handles in succession.

When the application has finished the enumeration, the enumeration handle must be destroyed with the [WinEndEnumWindows](#) call.

WinBeginEnumWindows - Parameters

hwnd ([HWND](#)) - input

Handle of the window whose child windows are to be enumerated.

HWND_DESKTOP

Enumerate all main windows

HWND_OBJECT

Enumerate all object windows

Other

Enumerate all immediate children of the specified window.

henumHenum ([HENUM](#)) - returns

Enumeration handle.

This is used in subsequent calls to the [WinGetNextWindow](#) function to return the immediate child-window handles in succession.

When the application has finished the enumeration, the enumeration handle must be destroyed with the [WinEndEnumWindows](#) call.

WinBeginEnumWindows - Remarks

This function remembers the window hierarchy at the time of invocation of the call. Thereafter the information is referenced by use of the *henum/henum* parameter and does not change during the enumeration by the [WinGetNextWindow](#) call. The windows are enumerated in the z-order at the time enumeration is begun, with the topmost child window enumerated first.

Only the immediate children of the specified window are enumerated; child windows of the child windows are excluded.

The enumerated windows are not locked by this function and can thus be destroyed between the time that it is called and the time that the [WinGetNextWindow](#) function is used to obtain the handle for the window.

WinBeginEnumWindows - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinBeginEnumWindows - Example Code

This example begins window enumeration of all main windows (i.e. all immediate children of the Desktop), after which [WinGetNextWindow](#) is called in a loop to enumerate all the children, until all children are found and the enumeration ends.

```
#define INCL_WINWINDOWMGR      /* Window Manager Functions */
#include <os2.h>

HWND  hwndParent;             /* Handle of the window whose child windows
                                are to be enumerated */
HWND  hwndNext;               /* current enumeration handle */
HENUM henum;                  /* enumeration handle */
BOOL  fSuccess;               /* success indicator */
SHORT sRetLen;                /* returned string length */
SHORT sLength = 10;           /* string buffer length */
char  pchBuffer[10];          /* string buffer */

hwndParent = HWND_DESKTOP;

henum = WinBeginEnumWindows(hwndParent);
```

```

while ((hwndNext = WinGetNextWindow(henum)) != NULLHANDLE) {
    .
    .
}

fSuccess = WinEndEnumWindows (henum);

```

WinBeginPaint

WinBeginPaint - Syntax

This function obtains a presentation space whose associated update region is set ready for drawing in a specified window.

```

#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HWND      hwnd;          /* Handle of window where drawing is going to occur. */
HPS       hps;           /* Presentation-space handle. */
PRECTL    prclPaint;     /* Bounding rectangle. */
HPS       hpsPaintPS;    /* Presentation-space handle. */

hpsPaintPS = WinBeginPaint(hwnd, hps, prclPaint);

```

WinBeginPaint Parameter - hwnd

hwnd ([HWND](#)) - input

Handle of window where drawing is going to occur.

HWND_DESKTOP

The desk top window.

Other

Specified window.

WinBeginPaint Parameter - hps

hps ([HPS](#)) - input

Presentation-space handle.

NULLHANDLE

Obtain a cache presentation space.

Other

Presentation-space handle. This function sets its clipping region to the update region of the *hwnd* parameter.

WinBeginPaint Parameter - prclPaint

prclPaint ([PRECTL](#)) - output

Bounding rectangle.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) can also be used, if supported by the language.

NULL

No bounding rectangle; that is, there is no need of changing any point.

Other

Specifies the smallest rectangle bounding the update region, in window coordinates.

WinBeginPaint Return Value - hpsPaintPS

hpsPaintPS ([HPS](#)) - returns

Presentation-space handle.

NULLHANDLE

Error occurred

Other

Presentation-space handle.

WinBeginPaint - Parameters

hwnd ([HWND](#)) - input

Handle of window where drawing is going to occur.

HWND_DESKTOP

The desk top window.

Other

Specified window.

hps ([HPS](#)) - input

Presentation-space handle.

NULLHANDLE

Obtain a cache presentation space.

Other

Presentation-space handle. This function sets its clipping region to the update region of the *hwnd* parameter.

prclPaint ([PRECTL](#)) - output

Bounding rectangle.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) can also be used, if supported by the language.

NULL

No bounding rectangle; that is, there is no need of changing any point.

Other

Specifies the smallest rectangle bounding the update region, in window coordinates.

hpsPaintPS ([HPS](#)) - returns

Presentation-space handle.

NULLHANDLE

Error occurred

Other

Presentation-space handle.

WinBeginPaint - Remarks

This function is generally call during the processing of a [WM_PAINT](#) message when the application needs to update the content of the window.

If the presentation space already exists, its update region is set and the device context of the window is associated with the presentation space. Otherwise, a cache presentation space is obtained specifically for the window.

The update region associated with *hwnd* is reset to NULLHANDLE. It is assumed that any drawing following this function restores the content of the window to a fully correct state.

This function hides the pointer if it is in the window and the [WinEndPaint](#) function restores it.

This function hides the tracking rectangle if it is active and might hide part of the painting window; that is, if *hwnd* is a child of the window specified by the *hwnd* parameter in the [WinTrackRect](#) function. The [WinEndPaint](#) function shows it again.

[WinEndPaint](#) must be called after the application completes drawing, and can be nested for the same window.

WinBeginPaint - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)

An invalid window handle was specified.

PMERR_INV_HPS (0x207F)

An invalid presentation-space handle was specified.

WinBroadcastMsg

WinBroadcastMsg - Syntax

This function broadcasts a message to multiple windows.

```
#define INCL_WINMESSAGEGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwndParent; /* Parent-window handle. */
ULONG     ulMsgId;     /* Message identifier. */
MPARAM    mpParam1;    /* Parameter 1. */
MPARAM    mpParam2;    /* Parameter 2. */
ULONG     flCmd;       /* Broadcast message command. */
BOOL      rc;          /* Success indicator. */

rc = WinBroadcastMsg(hwndParent, ulMsgId,
                    mpParam1, mpParam2, flCmd);
```

WinBroadcastMsg Parameter - hwndParent

hwndParent ([HWND](#)) - input
Parent-window handle.

WinBroadcastMsg Parameter - ulMsgId

ulMsgId ([ULONG](#)) - input
Message identifier.

WinBroadcastMsg Parameter - mpParam1

mpParam1 (MPARAM) - input
Parameter 1.

WinBroadcastMsg Parameter - mpParam2

mpParam2 (MPARAM) - input
Parameter 2.

WinBroadcastMsg Parameter - flCmd

flCmd (ULONG) - input
Broadcast message command.

- BMSG_POST
Post the message. This value is mutually exclusive with BMSG_SEND and BMSG_POSTQUEUE.
- BMSG_SEND
Send the message. This value is mutually exclusive with BMSG_POST and BMSG_POSTQUEUE.
- BMSG_POSTQUEUE
Post a message to all threads that have a message queue. This value is mutually exclusive with BMSG_POST and BMSG_SEND. The *hwnd* parameter of the QMSG structure is set to NULL.
- BMSG_DESCENDANTS
Broadcast the message to all the descendants of the *hwndParent* parameter.
- BMSG_FRAMEONLY
Broadcast the message only to windows with a style of CS_FRAME.

WinBroadcastMsg Return Value - rc

rc (BOOL) - returns
Success indicator.

- TRUE
Message was sent or posted successfully to all applicable windows
- FALSE
Error occurred.

WinBroadcastMsg - Parameters

hwndParent ([HWND](#)) - input
Parent-window handle.

ulMsgId ([ULONG](#)) - input
Message identifier.

mpParam1 ([MPARAM](#)) - input
Parameter 1.

mpParam2 ([MPARAM](#)) - input
Parameter 2.

flCmd ([ULONG](#)) - input
Broadcast message command.

BMSG_POST
Post the message. This value is mutually exclusive with **BMSG_SEND** and **BMSG_POSTQUEUE**.

BMSG_SEND
Send the message. This value is mutually exclusive with **BMSG_POST** and **BMSG_POSTQUEUE**.

BMSG_POSTQUEUE
Post a message to all threads that have a message queue. This value is mutually exclusive with **BMSG_POST** and **BMSG_SEND**. The *hwnd* parameter of the [QMSG](#) structure is set to NULL.

BMSG_DESCENDANTS
Broadcast the message to all the descendants of the *hwndParent* parameter.

BMSG_FRAMEONLY
Broadcast the message only to windows with a style of **CS_FRAME**.

rc ([BOOL](#)) - returns
Success indicator.

TRUE
Message was sent or posted successfully to all applicable windows

FALSE
Error occurred.

WinBroadcastMsg - Remarks

This function sends or posts a message to all the immediate child windows of *hwndParent*, except in the case when *flCmd* is **BMSG_DESCENDANTS**.

The *ulMsgId*, *mpParam1*, and *mpParam2* parameters make up the message sent or posted. The window handle of the receiving window is added to the message.

WinCalcFrameRect

WinCalcFrameRect - Syntax

This function calculates a client rectangle from a frame rectangle, or a frame rectangle from a client rectangle.

```
#define INCL_WINFRAMEMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND     hwndFrame; /* Frame-window handle. */
PRECTL   prcl;      /* Window rectangle. */
BOOL     fClient;   /* Frame indicator. */
BOOL     rc;         /* Rectangle-calculated indicator. */

rc = WinCalcFrameRect(hwndFrame, prcl, fClient);
```

WinCalcFrameRect Parameter - hwndFrame

hwndFrame ([HWND](#)) - input
Frame-window handle.

WinCalcFrameRect Parameter - prcl

prcl ([PRECTL](#)) - in/out
Window rectangle.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) can also be used, if supported by the language.

WinCalcFrameRect Parameter - fClient

fClient ([BOOL](#)) - input
Frame indicator.

TRUE	Frame rectangle provided
FALSE	Client-area rectangle provided.

WinCalcFrameRect Return Value - rc

rc ([BOOL](#)) - returns
Rectangle-calculated indicator.

TRUE	Rectangle successfully calculated
FALSE	Error occurred, or the calculated rectangle is empty.

WinCalcFrameRect - Parameters

hwndFrame ([HWND](#)) - input
Frame-window handle.

prcl ([PRECTL](#)) - in/out
Window rectangle.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) can also be used, if supported by the language.

fClient ([BOOL](#)) - input
Frame indicator.

TRUE	Frame rectangle provided
FALSE	Client-area rectangle provided.

rc ([BOOL](#)) - returns
Rectangle-calculated indicator.

TRUE	Rectangle successfully calculated
FALSE	Error occurred, or the calculated rectangle is empty.

WinCalcFrameRect - Remarks

In order for WinCalcFrameRect to perform its calculations correctly, the window rectangle in *prcl* must be specified in screen coordinates. The WinMapWindowPoints function is called to make the conversion from client coordinates to screen coordinates, as shown in the example code.

WinCalcFrameRect provides the size and position of the client area within the specified frame rectangle for the specified frame window, or conversely, the size and position of the frame window that would contain a client window of the specified size and position.

WinCalcFrameRect sends a [WM_CALCFRAMERECT](#) message to the frame window. This enables a subclassed frame control to implement the calculation correctly.

This function works if *hwndFrame* is hidden; *hwndFrame* should be hidden if it is required that the window shows a particular client rectangle when the window is first shown.

WinCalcFrameRect - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinCallMsgFilter

WinCallMsgFilter - Syntax

This function calls a message-filter hook.

```
#define INCL_WINHOOKS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
PQMSG    pqmsg;        /* Message to be passed to the message-filter hook. */
ULONG    ulFilter;     /* Filter. */
BOOL     rc;           /* Message-filter hook return indicator. */

rc = WinCallMsgFilter(hab, pqmsg, ulFilter);
```

WinCallMsgFilter Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinCallMsgFilter Parameter - pqmsg

pqmsg ([PQMSG](#)) - input
Message to be passed to the message-filter hook.

WinCallMsgFilter Parameter - ulFilter

ulFilter (**ULONG**) - input
Filter.

Message-filter code passed to the message-filter hook. This can be an application-specific value or one of the following standard MSGF_* values:

MSGF_DIALOGBOX
Dialog-box mode loop.

MSGF_TRACK
Window-movement and size tracking. When this hook is used the **TRACKINFO** structure specified the *ptiTrackinfo* parameter of the **WinTrackRect** function is updated to give the current state before the hook is called. Only the *rcTrack* and the *fs* parameters are updated.

MSGF_DRAG
Direct manipulation mode loop.

MSGF_DDEPOSTMSG
DDE post message mode loop.

WinCallMsgFilter Return Value - rc

rc (**BOOL**) - returns
Message-filter hook return indicator.

TRUE
A message-filter hook returns TRUE

FALSE
All message-filter hooks return FALSE, or no message-filter hooks are defined.

WinCallMsgFilter - Parameters

hab (**HAB**) - input
Anchor-block handle.

pqmsg (**PQMSG**) - input
Message to be passed to the message-filter hook.

ulFilter (**ULONG**) - input
Filter.

Message-filter code passed to the message-filter hook. This can be an application-specific value or one of the following standard MSGF_* values:

MSGF_DIALOGBOX
Dialog-box mode loop.

MSGF_TRACK
Window-movement and size tracking. When this hook is used the **TRACKINFO** structure specified the *ptiTrackinfo* parameter of the **WinTrackRect** function is updated to give the current state before the hook is called. Only the *rcTrack* and the *fs* parameters are updated.

MSGF_DRAG
Direct manipulation mode loop.

MSGF_DDEPOSTMSG
DDE post message mode loop.

rc ([BOOL](#)) - returns
Message-filter hook return indicator.

TRUE
A message-filter hook returns TRUE

FALSE
All message-filter hooks return FALSE, or no message-filter hooks are defined.

WinCallMsgFilter - Remarks

This function allows an application to pass a message to the message-filter hook procedure(s).

WinCancelShutdown

WinCancelShutdown - Syntax

This function cancels a request for an application to shut down.

```
#define INCL_WINMESSAGEGR /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HMQ      hmq;          /* Handle of message queue for current thread. */
BOOL      fCancelAlways; /* Cancellation control. */
BOOL      rc;           /* Success indicator. */

rc = WinCancelShutdown(hmq, fCancelAlways);
```

WinCancelShutdown Parameter - hmq

hmq ([HMQ](#)) - input

Handle of message queue for current thread.

WinCancelShutdown Parameter - fCancelAlways

fCancelAlways ([BOOL](#)) - input

Cancellation control.

TRUE

No [WM_QUIT](#) message should be placed on this queue during system shutdown.

FALSE

The applications ignore any outstanding [WM_QUIT](#) messages already sent to it, but a message should be sent during other system shutdowns.

WinCancelShutdown Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinCancelShutdown - Parameters

hmq (**HMQ**) - input
Handle of message queue for current thread.

fCancelAlways (**BOOL**) - input
Cancellation control.

TRUE	No WM_QUIT message should be placed on this queue during system shutdown.
FALSE	The applications ignore any outstanding WM_QUIT messages already sent to it, but a message should be sent during other system shutdowns.

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinCancelShutdown - Remarks

On a system shutdown, each message queue normally posts a **WM_QUIT** message. An application can then handle this message in one of the three ways:

- Destroy its message queue using `WinDestroyMsgQueue (hmq)`.
- Call `WinCancelShutdown (hmq, TRUE)` to prevent the current thread's event queue from receiving the **WM_QUIT** messages when the system is shut down. This does not stop other threads from receiving this message.
- Call `WinCancelShutdown (hmq, FALSE)` to remove all pending **WM_QUIT** messages from the current thread's event queue but allow future **WM_QUIT** messages to be posted.

Either way, the system can proceed to the next queue.

WinChangeSwitchEntry

WinChangeSwitchEntry - Syntax

This function changes the information in a Window List entry.

```
#define INCL_WINSWITCHLIST /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

H SWITCH    hswitchSwitch; /* Handle to the Window List entry to be changed. */
SWC NTRL    swctlSwitchData; /* Switch-control data. */
ULONG       ulRetCode; /* Return code. */

ulRetCode = WinChangeSwitchEntry(hswitchSwitch,
                                swctlSwitchData);
```

WinChangeSwitchEntry Parameter - hswitchSwitch

hswitchSwitch ([H SWITCH](#)) - input
Handle to the Window List entry to be changed.

WinChangeSwitchEntry Parameter - swctlSwitchData

swctlSwitchData ([SWC NTRL](#)) - input
Switch-control data.

Contains the information to change the Window List entry.

If the *idProcess* field of the [SWC NTRL](#) structure is 0, the current process ID is used.

If the *idSession* field of the [SWC NTRL](#) structure is 0, the current session ID is used.

WinChangeSwitchEntry Return Value - ulRetCode

ulRetCode ([ULONG](#)) - returns
Return code.

0	Successful completion
Other	Error occurred.

WinChangeSwitchEntry - Parameters

hswitchSwitch ([HSWITCH](#)) - input
Handle to the Window List entry to be changed.

swctlSwitchData ([SWCNTRL](#)) - input
Switch-control data.

Contains the information to change the Window List entry.

If the *idProcess* field of the [SWCNTRL](#) structure is 0, the current process ID is used.

If the *idSession* field of the [SWCNTRL](#) structure is 0, the current session ID is used.

ulRetCode ([ULONG](#)) - returns
Return code.

0	Successful completion
Other	Error occurred.

WinChangeSwitchEntry - Remarks

Leading and trailing blanks are removed from the title and, if necessary, it is truncated to 60 characters.

WinChangeSwitchEntry - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_SWITCH_HANDLE (0x1202)
An invalid Window List entry handle was specified.

PMERR_INVALID_WINDOW (0x1206)
The window specified with a Window List call is not a valid frame window.

WinChangeSwitchEntry - Example Code

This example changes the program name of a task-list entry to "Generic: NEW.APP" using the handle returned by WinAddSwitchEntry.

```
#define INCL_WINSWITCHLIST      /* Window Switch List Functions */
#define INCL_WINWINDOWMGR      /* Window Manager Functions */
#include <os2.h>

HSWITCH hswitch;               /* task-list entry handle */
SWCNTRL swctl;                 /* switch-control data */
PID pid;                       /* process id */
HAB hab;                       /* anchor-block handle */
HWND hwndFrame;                /* frame handle */

hab = WinQueryAnchorBlock(hwndFrame); /* gets anchor block */
WinQueryWindowProcess(hwndFrame, &pid, NULL); /* gets process id */

/* initialize switch structure */
swctl.hwnd = hwndFrame;         /* window handle */
```

```

swctl.hwndIcon = NULLHANDLE;          /* icon handle          */
swctl.hprog = NULLHANDLE;             /* program handle      */
swctl.idProcess = pid;                /* process identifier  */
swctl.idSession = 0;                 /* session identifier  */
swctl.uchVisibility = SWL_VISIBLE;    /* visibility          */
swctl.fbJump = SWL_JUMPABLE;         /* jump indicator      */
swctl.szSwttitle[0]= 0;              /* program name        */

hswitch = WinCreateSwitchEntry(hab, &swctl);

/* set application name */
strcpy(swctl.szSwttitle, "Generic: NEW.APP");

WinChangeSwitchEntry(hswitch, &swctl);

```

WinCheckButton

WinCheckButton - Syntax

This macro sets the checked state of the specified button control. It returns the previous check state.

```

#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwndDlg;      /* Dialog window handle. */
USHORT    usId;         /* Button control identity. */
USHORT    usChkstate;   /* Indicates the current checked state of the button. */
USHORT    usRetChkst;   /* Returns the previous checkstate. */

usRetChkst = WinCheckButton(hwndDlg, usId,
                             usChkstate);

```

WinCheckButton Parameter - hwndDlg

hwndDlg ([HWND](#)) - input
Dialog window handle.

WinCheckButton Parameter - usId

usId ([USHORT](#)) - input
Button control identity.

WinCheckButton Parameter - usChkstate

usChkstate ([USHORT](#)) - input
Indicates the current checked state of the button.

WinCheckButton Return Value - usRetChkst

usRetChkst ([USHORT](#)) - returns
Returns the previous checkstate.

WinCheckButton - Parameters

hwndDlg ([HWND](#)) - input
Dialog window handle.

usId ([USHORT](#)) - input
Button control identity.

usChkstate ([USHORT](#)) - input
Indicates the current checked state of the button.

usRetChkst ([USHORT](#)) - returns
Returns the previous checkstate.

WinCheckButton - Remarks

This macro expands to:

```
#define WinCheckButton(hwndDlg, usId, usChkstate)
```

```

((USHORT)WinSendDlgItemMsg(hwndDlg,
                             usId,
                             BM_SETCHECK,
                             MPFROMSHORT(usChkstate),
                             (MPARAM)NULL))

```

This call requires the existence of a message queue.

WinCheckInput

WinCheckInput - Syntax

This function is specific to OS/2 Version 2.1 or higher.

This function is used in conjunction with the [MsgInputHook](#) hook to input simulated events into the Presentation Manager input processing system.

```
#define INCL_WININPUT /* Or use INCL_WIN, INCL_PM, */  
#include <os2.h>  
  
HAB    hab; /* The application anchor block. */  
BOOL    rc; /* Return code. */  
  
rc = WinCheckInput(hab);
```

WinCheckInput Parameter - hab

hab ([HAB](#)) - input
The application anchor block.

WinCheckInput Return Value - rc

rc ([BOOL](#)) - returns
Return code.

TRUE	The system checked for mouse and keyboard input.
FALSE	An error occurred.

WinCheckInput - Parameters

hab ([HAB](#)) - input
The application anchor block.

rc ([BOOL](#)) - returns
Return code.

TRUE	The system checked for mouse and keyboard input.
FALSE	An error occurred.

WinCheckInput - Remarks

This function must be called whenever an application injects simulated mouse or keyboard events using [MsgInputHook](#), otherwise there is no guarantee when those simulated events will occur. It forces the Presentation Manager input processing system to wake up and take a look at all possible sources of input events: the [MsgInputHook](#) hook, the [JournalPlaybackHook](#) hook, and the Presentation Manager input queue that contains normal mouse and keyboard events.

WinCheckMenuItem

WinCheckMenuItem - Syntax

This macro sets the check state of the specified menu item to the flag.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwndMenu; /* Menu window handle. */
USHORT    usId;      /* Item identifier. */
BOOL      fCheck;    /* Check flag. */
BOOL      rc;         /* Success indicator. */

rc = WinCheckMenuItem(hwndMenu, usId, fCheck);
```

WinCheckMenuItem Parameter - hwndMenu

hwndMenu (**HWND**) - input
Menu window handle.

WinCheckMenuItem Parameter - usId

usId (**USHORT**) - input
Item identifier.

WinCheckMenuItem Parameter - fCheck

fCheck (**BOOL**) - input
Check flag.

WinCheckMenuItem Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinCheckMenuItem - Parameters

hwndMenu ([HWND](#)) - input
Menu window handle.

usId ([USHORT](#)) - input
Item identifier.

fCheck ([BOOL](#)) - input
Check flag.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinCheckMenuItem - Remarks

This macro expands to:

```
#define WinCheckMenuItem(hwndMenu, usId, fCheck)
((BOOL)WinSendMsg(hwndMenu,
    MM_SETITEMATTR,
    MPFROM2SHORT(usId, TRUE),
    MPFROM2SHORT(MIA_CHECKED, (BOOL)(fCheck) ? MIA_CHECKED : 0)))
```

This function requires the existence of a message queue.

This function closes the clipboard, allowing other applications to open it with the [WinOpenClipbrd](#) function.

```
#define INCL_WINCLIPBOARD /* Or use INCL_WIN, INCL_PM, */
```

```
#include <os2.h>

HAB    hab; /* Anchor-block handle. */
BOOL    rc; /* Success indicator. */

rc = WinCloseClipbrd(hab);
```

WinCloseClipbrd Parameter - hab

hab (**HAB**) - input
Anchor-block handle.

WinCloseClipbrd Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinCloseClipbrd - Parameters

hab (**HAB**) - input
Anchor-block handle.

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinCloseClipbrd - Remarks

This function causes the contents of the clipboard to be drawn in the clipboard viewer window (if any), by sending it a [WM_DRAWCLIPBOARD](#) message. This action occurs only if the clipboard data has changed.

The clipboard must be open before this function is invoked.

WinCompareStrings

WinCompareStrings - Syntax

Compares two null-terminated strings defined using the same code page.

```
#define INCL_WINCOUNTRY /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;           /* Anchor-block handle. */
ULONG    idCodepage;    /* Code page identity of both strings. */
ULONG    idCountryCode; /* Country code. */
PSZ      pszString1;    /* String 1. */
PSZ      pszString2;    /* String 2. */
ULONG    ulReserved;    /* Reserved value, should be 0. */
ULONG    ulResult;      /* Comparison result. */

ulResult = WinCompareStrings(hab, idCodepage,
                             idCountryCode, pszString1, pszString2,
                             ulReserved);
```

WinCompareStrings Parameter - hab

hab (**HAB**) - input
Anchor-block handle.

WinCompareStrings Parameter - idCodepage

idCodepage (**ULONG**) - input
Code page identity of both strings.

If *idCodepage* is set to 0, the current code page of the caller is used.

WinCompareStrings Parameter - idCountryCode

idCountryCode (**ULONG**) - input
Country code.

If *idCountryCode* is set to 0, the country information for the default system country code is used.

WinCompareStrings Parameter - pszString1

pszString1 ([PSZ](#)) - input
String 1.

WinCompareStrings Parameter - pszString2

pszString2 ([PSZ](#)) - input
String 2.

WinCompareStrings Parameter - ulReserved

ulReserved ([ULONG](#)) - input
Reserved value, should be 0.

WinCompareStrings Return Value - ulResult

ulResult ([ULONG](#)) - returns
Comparison result.

WCS_EQ	Strings are equal
WCS_LT	String 1 is less than string 2
WCS_GT	String 1 is greater than string 2
WCS_ERROR	Error occurred.

WinCompareStrings - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

idCodepage ([ULONG](#)) - input
Code page identity of both strings.

If *idCodepage* is set to 0, the current code page of the caller is used.

idCountryCode ([ULONG](#)) - input
Country code.

If *idCountryCode* is set to 0, the country information for the default system country code is used.

pszString1 ([PSZ](#)) - input
String 1.

pszString2 ([PSZ](#)) - input
String 2.

ulReserved ([ULONG](#)) - input
Reserved value, should be 0.

ulResult ([ULONG](#)) - returns
Comparison result.

WCS_EQ	Strings are equal
WCS_LT	String 1 is less than string 2
WCS_GT	String 1 is greater than string 2
WCS_ERROR	Error occurred.

WinCompareStrings - Remarks

The first code page of either of the two ASCII code pages specified in CONFIG.SYS is used as the system default. The following is the list of valid code pages:

Country	Code Page
Canadian-French	863
Desktop Publishing	1004
Iceland	861
Latin 1 Multilingual	850
Latin 2 Multilingual	852
Nordic	865
Portuguese	860
Turkey	857
U.S. (IBM PC)	437

Code page 1004 is compatible with Microsoft** Windows**.

The following EBCDIC code pages, based on character set 697, are also available for output:

Country	Code Page
Austrian/German	273
Belgian	500
Brazil	037
Czechoslovakia	870
Danish/Norwegian	277
Finnish/Swedish	278

WinCompareStrings - Example Code

This example compares two strings using the same code page: the first string is loaded from a resource DLL, while the second is created by the application.

```
#define INCL_WINCOUNTRY          /* Window Country Functions */
```

```

#define INCL_WINWINDOWMGR      /* Window Manager Functions */
#define INCL_DOSMODULEMGR      /* Module Manager Functions */
#include <os2.h>

ULONG   ulResult;              /* comparison result */
HAB     hab;                   /* anchor-block handle */
ULONG   idCodepage=437; /* Code page identity of both strings */
ULONG   idCountryCode=1; /* Country code */
char     pszString1[10]; /* first string */
char     pszString2[10]; /* second string */
LONG     lLength;              /* length of string */
ULONG   idString = STRING_ID; /* String identifier */
LONG     lBufferMax = 10; /* Size of buffer */
HMODULE  hmodDLL;              /* Handle of the module which contains
                                the help table and help subtable
                                resources. */
CHAR     LoadError[100]; /* object name buffer for DosLoad */
ULONG    rc;                   /* return code */

/* obtain resource handle */
rc = DosLoadModule(LoadError, sizeof(LoadError), "RES.DLL",
                  &hmodDLL);

/* load string from resource */
if (rc == 0)
    lLength = WinLoadString(hab, hmodDLL, idString, lBufferMax,
                          pszString1);

/* compare strings */
if (lLength > 0)
{
    /* set second string */
    strcpy(pszString2, "Compare");

    ulResult = WinCompareStrings(hab, idCodepage, idCountryCode,
                                pszString1, pszString2, 0);
}

WinCopyAccelTable

WinCopyAccelTable - Syntax

This function is used to get the accelerator-table data corresponding to an accelerator-table handle, or to determine the size of the

accelerator-table data.

```
#define INCL_WINACCELERATORS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HACCEL      hAccel;          /* Accelerator-table handle. */
PACCELTABLE pacctAccelTable; /* Accelerator-table data area. */
ULONG       ulCopyMax;       /* Maximum data area size. */
ULONG       ulCopied;        /* Amount copied or size required. */

ulCopied = WinCopyAccelTable(hAccel, pacctAccelTable,
                             ulCopyMax);
```

WinCopyAccelTable Parameter - hAccel

hAccel (**HACCEL**) - input
Accelerator-table handle.

WinCopyAccelTable Parameter - pacctAccelTable

pacctAccelTable (**PACCELTABLE**) - in/out
Accelerator-table data area.

- | | |
|-------|--|
| NULL | Return the size, in bytes, of the complete accelerator table, and ignore the <i>ulCopyMax</i> parameter. |
| Other | Copy up to <i>ulCopyMax</i> bytes of the accelerator table into this data area. |

WinCopyAccelTable Parameter - ulCopyMax

ulCopyMax (**ULONG**) - input
Maximum data area size.

WinCopyAccelTable Return Value - ulCopied

ulCopied (**ULONG**) - returns
Amount copied or size required.

- | | |
|-------|---|
| Other | Amount of data copied into the data area, or the size of data area required for the complete accelerator table. |
|-------|---|

0

Error occurred.

WinCopyAccelTable - Parameters

hAccel ([HACCEL](#)) - input
Accelerator-table handle.

pacctAccelTable ([PACCELTABLE](#)) - in/out
Accelerator-table data area.

NULL

Return the size, in bytes, of the complete accelerator table, and ignore the *uiCopyMax* parameter.

Other

Copy up to *uiCopyMax* bytes of the accelerator table into this data area.

uiCopyMax ([ULONG](#)) - input
Maximum data area size.

uiCopied ([ULONG](#)) - returns
Amount copied or size required.

Other

Amount of data copied into the data area, or the size of data area required for the complete accelerator table.

0

Error occurred.

WinCopyAccelTable - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HACCEL (0x101A)
An invalid accelerator-table handle was specified.

WinCopyObject

WinCopyObject - Syntax

This function is specific to OS/2 Version 3.0 or higher.

This function copies an object from its existing location to a specified new destination.

```
#define INCL_WINWORKPLACE
#include <os2.h>

HOBJECT    hObjectofObject; /* Handle of the Workplace Shell object being copied. */
HOBJECT    hObjectofDest;   /* Handle of the destination folder into which hObjectofObject is to be copied. */
ULONG      ulReserved;      /* Reserved value; must be 0. */
HOBJECT    rc;              /* Handle of the newly created object. */

rc = WinCopyObject(hObjectofObject, hObjectofDest,
                   ulReserved);
```

WinCopyObject Parameter - hObjectofObject

hObjectofObject ([HOBJECT](#)) - input
Handle of the Workplace Shell object being copied.

WinCopyObject Parameter - hObjectofDest

hObjectofDest ([HOBJECT](#)) - input
Handle of the destination folder into which *hObjectofObject* is to be copied.

WinCopyObject Parameter - ulReserved

ulReserved ([ULONG](#)) - input
Reserved value; must be 0.

WinCopyObject Return Value - rc

rc ([HOBJECT](#)) - returns
Handle of the newly created object.

A return value of NULLHANDLE indicates that either *hObjectofDest* is NULLHANDLE or an object with the same name as *hObjectofObject* exists in the destination folder.

WinCopyObject - Parameters

hObjectofObject ([HOBJECT](#)) - input
Handle of the Workplace Shell object being copied.

hObjectofDest ([HOBJECT](#)) - input
Handle of the destination folder into which *hObjectofObject* is to be copied.

ulReserved ([ULONG](#)) - input
Reserved value; must be 0.

rc ([HOBJECT](#)) - returns
Handle of the newly created object.

A return value of NULLHANDLE indicates that either *hObjectofDest* is NULLHANDLE or an object with the same name as *hObjectofObject* exists in the destination folder.

WinCopyObject - Remarks

Using [HOBJECT](#)s for .INI files or files in which an application uses a rename/save/delete sequence is not supported. Its REXX counterpart is SysCopyObject.

WinCopyObject - Errors

Possible returns from [WinGetLastError](#)

WPERR_INVALID_FLAGS (0x1719)
An invalid flag was specified.

WinCopyObject - Example Code

This example copies the drives object into the startup folder; the drives folder will be opened at the startup of the system.

```
#define INCL_WINWORKPLACE
#include "os2.h"

HOBJECT    hObjectofDest;
HOBJECT    hObjectofObject;
HOBJECT    hObjectofResult;

hObjectofObject = WinQueryObject("<WP_DRIVES>");
if (hObjectofObject != NULL)
{
    /* WinQueryObject of Drives was successful */
    hObjectofDest = WinQueryObject("<WP_START>");

    if (hObjectofDest != NULL)
    {
        /* WinQueryObject of Startup was successful */
        hObjectofResult = WinCopyObject(hObjectofObject, hObjectofDest, 0);

        if (hObjectofResult != NULL)
        {
            /* Drives Object was successfully copied to the Startup Folder */
```

```
    }
    else
    {
        /* Copy failed */
    }
}
}

WinCopyRect

WinCopyRect - Syntax

This function copies a rectangle from *prclSrc* to *prclDst*.

```
#define INCL_WINRECTANGLES /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>
```

```
HAB      hab;          /* Anchor-block handle. */
PRECTL   prclDst;       /* Destination rectangle. */
PRECTL   prclSrc;       /* Source rectangle. */
BOOL      rc;           /* Success indicator. */
```

```
rc = WinCopyRect(hab, prclDst, prclSrc);
```

WinCopyRect Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinCopyRect Parameter - prclDst

prclDst ([PRECTL](#)) - output
Destination rectangle.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) can also be used, if supported by the language.

WinCopyRect Parameter - prclSrc

prclSrc ([PRECTL](#)) - input
Source rectangle.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) can also be used, if supported by the language.

WinCopyRect Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinCopyRect - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

prclDst ([PRECTL](#)) - output
Destination rectangle.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) can also be used, if supported by the language.

prclSrc ([PRECTL](#)) - input
Source rectangle.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) can also be used, if supported by the language.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinCpTranslateChar

WinCpTranslateChar - Syntax

This function translates a character from one code page to another.

```
#define INCL_WINCOUNTRY /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
ULONG    idCpSource;   /* Source-character code page. */
UCHAR    ucSource;     /* Character to be translated. */
ULONG    idCpDest;     /* Code page of the resultant character. */
UCHAR    ucDest;       /* If nonzero, the translated or substitution (0xFF) character. */

ucDest = WinCpTranslateChar(hab, idCpSource,
                           ucSource, idCpDest);
```

WinCpTranslateChar Parameter - hab

hab (**HAB**) - input
Anchor-block handle.

WinCpTranslateChar Parameter - idCpSource

idCpSource (**ULONG**) - input
Source-character code page.

WinCpTranslateChar Parameter - ucSource

ucSource (**UCHAR**) - input
Character to be translated.

WinCpTranslateChar Parameter - idCpDest

idCpDest ([ULONG](#)) - input
Code page of the resultant character.

WinCpTranslateChar Return Value - ucDest

ucDest ([UCHAR](#)) - returns
If nonzero, the translated or substitution (0xFF) character.

WinCpTranslateChar - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

idCpSource ([ULONG](#)) - input
Source-character code page.

ucSource ([UCHAR](#)) - input
Character to be translated.

idCpDest ([ULONG](#)) - input
Code page of the resultant character.

ucDest ([UCHAR](#)) - returns
If nonzero, the translated or substitution (0xFF) character.

WinCpTranslateChar - Remarks

Successful invocation of this function indicates that either (1) the character was directly mapped into the destination code page or, (2) the substitution character (0xFF) was returned.

The following is the list of valid code pages:

Country	Code Page

WinCpTranslateString Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinCpTranslateString Parameter - idCpSource

idCpSource (ULONG) - input
Source-string code page.

WinCpTranslateString Parameter - pszSource

pszSource (PSZ) - input
String to be translated.

This is a null-terminated string.

WinCpTranslateString Parameter - idCpDest

idCpDest (ULONG) - input
Code page of the resultant string.

WinCpTranslateString Parameter - cbLenDest

cbLenDest (ULONG) - input
Maximum length of output string.

An error is raised if this is not large enough to contain the translated string.

WinCpTranslateString Parameter - pszDest

pszDest (PSZ) - output
The translated string.

This is a null-terminated string.

WinCpTranslateString Return Value - rc

rc (BOOL) - returns
Success indicator.

TRUE
Successful completion

FALSE

Error occurred.

WinCpTranslateString - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

idCpSource ([ULONG](#)) - input
Source-string code page.

pszSource ([PSZ](#)) - input
String to be translated.

This is a null-terminated string.

idCpDest ([ULONG](#)) - input
Code page of the resultant string.

cbLenDest ([ULONG](#)) - input
Maximum length of output string.

An error is raised if this is not large enough to contain the translated string.

pszDest ([PSZ](#)) - output
The translated string.

This is a null-terminated string.

rc ([BOOL](#)) - returns
Success indicator.

TRUE

Successful completion

FALSE

Error occurred.

WinCreateAtomTable

WinCreateAtomTable - Syntax

This function creates a private empty atom table.

```

#define INCL_WINATOM /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

ULONG      ulInitial;          /* Initial bytes. */
ULONG      ulBuckets;          /* Size of the hash table. */
HATOMTBL   hatomtblAtomTbl;    /* Atom-table handle. */

hatomtblAtomTbl = WinCreateAtomTable(ulInitial,
                                     ulBuckets);

```

WinCreateAtomTable Parameter - ulInitial

ulInitial (**ULONG**) - input
Initial bytes.

This parameter is ignored for **version 3, or higher**, of the OS/2 operating system. The *ulInitial* parameter is dynamically allocated. The initial number of bytes should be set to zero.

For **versions prior to version 3** of the OS/2 operating system, this parameter is the initial number of bytes to be reserved for the atom table. This is a lower bound on the amount of memory reserved. The amount of memory actually used by an atom table depends upon the actual number of atoms stored in the table. If zero, the size of the atom table is the minimum size needed to store the atom hash table. The minimum size of atom table allocated is $16 + (2 * ulBuckets)$.

WinCreateAtomTable Parameter - ulBuckets

ulBuckets (**ULONG**) - input
Size of the hash table.

Used to access atoms. If zero, the default value of 37 is used. The best results are achieved if a prime number is used.

WinCreateAtomTable Return Value - hatomtblAtomTbl

hatomtblAtomTbl (**HATOMTBL**) - returns
Atom-table handle.

NULLHANDLE

Call failed.

Other

Atom-table handle. This must be passed as a parameter in subsequent atom manager calls.

WinCreateAtomTable - Parameters

ulInitial (**ULONG**) - input

Initial bytes.

This parameter is ignored for **version 3, or higher**, of the OS/2 operating system. The *ulInitial* parameter is dynamically allocated. The initial number of bytes should be set to zero.

For **versions prior to version 3** of the OS/2 operating system, this parameter is the initial number of bytes to be reserved for the atom table. This is a lower bound on the amount of memory reserved. The amount of memory actually used by an atom table depends upon the actual number of atoms stored in the table. If zero, the size of the atom table is the minimum size needed to store the atom hash table. The minimum size of atom table allocated is $16+(2*ulBuckets)$.

ulBuckets (ULONG) - input
Size of the hash table.

Used to access atoms. If zero, the default value of 37 is used. The best results are achieved if a prime number is used.

hatomtblAtomTbl (HATOMTBL) - returns
Atom-table handle.

NULLHANDLE

Call failed.

Other

Atom-table handle. This must be passed as a parameter in subsequent atom manager calls.

WinCreateAtomTable - Remarks

The atom table is owned by the process from which this function is issued. It cannot be accessed directly from any other process. If it is still in existence when the process terminates, it will automatically be deleted by the system.

There is a system atom table which is created at boot time, which cannot be destroyed, and which can be accessed by any process in the system. The handle of the system atom table is queried with the [WinQuerySystemAtomTable](#) function.

WinCreateAtomTable - Example Code

This example creates an Atom Table of default size, adds the atom "newatom" to the new table, and then destroys the table.

```
#define INCL_WINATOM          /* Window Atom functions          */
#include <os2.h>

ATOM      atom;              /* New atom value              */
HATOMTBL  hatomtblAtomTbl;   /* Atom-table handle           */
HATOMTBL  hatomtblDestroy;   /* Result of destroy table     */
```

```

char      pszAtomName[10];    /* Atom name */
ULONG     ulInitial = 0;      /* Initial atom table size (use default) */
ULONG     ulBuckets = 0;      /* Size of hash table (use default) */

/* Create an atom table of the default size */
hAtomTblAtomTbl = WinCreateAtomTable(ulInitial, ulBuckets);

/* Define the name of the new atom and add it to the table */
strcpy(pszAtomName, "newatom");
atom = WinAddAtom(hAtomTblAtomTbl, pszAtomName);
hAtomTblDestroy = WinDestroyAtomTable(hAtomTblAtomTbl);

```

WinCreateCursor

WinCreateCursor - Syntax

This function creates or changes a cursor for a specified window.

```

#define INCL_WINCursors /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HWND     hwnd;    /* Handle of window in which cursor is displayed. */
LONG     lx;      /* x-position of cursor. */
LONG     ly;      /* y-position of cursor. */
LONG     lcx;     /* x-size of cursor. */
LONG     lcy;     /* y-size of cursor. */
ULONG     ulrgf;   /* Controls the appearance of the cursor. */
PRECTL   prclClip; /* Cursor rectangle. */
BOOL     rc;       /* Success indicator. */

rc = WinCreateCursor(hwnd, lx, ly, lcx, lcy,
    ulrgf, prclClip);

```

WinCreateCursor Parameter - hwnd

hwnd (**HWND**) - input

Handle of window in which cursor is displayed.

This must be the handle of a window for which the application can receive input.

WinCreateCursor Parameter - lx

lx (**LONG**) - input

x-position of cursor.

WinCreateCursor Parameter - ly

ly (**LONG**) - input

y-position of cursor.

WinCreateCursor Parameter - lcx

lcx (**LONG**) - input

x-size of cursor.

If 0, the system nominal border width (SV_CXBORDER) is used.

WinCreateCursor Parameter - lcy

lcy (**LONG**) - input

y-size of cursor.

If 0, the system nominal border height (SV_CYBORDER) is used.

WinCreateCursor Parameter - ulrgf

ulrgf (**ULONG**) - input

Controls the appearance of the cursor.

CURSOR_SOLID

The cursor is solid.

CURSOR_HALFTONE

The cursor is halftone.

CURSOR_FRAME

The cursor is a rectangular frame.

CURSOR_FLASH

The cursor flashes.

CURSOR_SETPOS

Set a new cursor position. *lx* and *ly* are ignored. Used when a cursor has already been created. In this case, all other appearance flags are ignored.

WinCreateCursor Parameter - prclClip

prclClip ([PRECTL](#)) - input

Cursor rectangle.

A rectangle within which the cursor is visible. If the cursor goes outside this rectangle, it is clipped away and is invisible.

The rectangle is specified in window coordinates.

If *prclClip* is NULL, the drawing of the cursor is clipped to the window rectangle of *hwnd*.

Note: The cursor is always clipped to the window rectangle, even if part of *prclClip* is outside it.

The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) can also be used, if supported by the language.

WinCreateCursor Return Value - rc

rc ([BOOL](#)) - returns

Success indicator.

TRUE

Successful completion

FALSE

Error occurred.

WinCreateCursor - Parameters

hwnd ([HWND](#)) - input

Handle of window in which cursor is displayed.

This must be the handle of a window for which the application can receive input.

lx ([LONG](#)) - input

x-position of cursor.

ly ([LONG](#)) - input
y-position of cursor.

lcx ([LONG](#)) - input
x-size of cursor.

If 0, the system nominal border width (SV_CXBORDER) is used.

lcy ([LONG](#)) - input
y-size of cursor.

If 0, the system nominal border height (SV_CYBORDER) is used.

ulrgf ([ULONG](#)) - input
Controls the appearance of the cursor.

CURSOR_SOLID
The cursor is solid.

CURSOR_HALFTONE
The cursor is halftone.

CURSOR_FRAME
The cursor is a rectangular frame.

CURSOR_FLASH
The cursor flashes.

CURSOR_SETPOS
Set a new cursor position. *lcx* and *lcy* are ignored. Used when a cursor has already been created. In this case, all other appearance flags are ignored.

prclClip ([PRECTL](#)) - input
Cursor rectangle.

A rectangle within which the cursor is visible. If the cursor goes outside this rectangle, it is clipped away and is invisible.

The rectangle is specified in window coordinates.

If *prclClip* is NULL, the drawing of the cursor is clipped to the window rectangle of *hwnd*.

Note: The cursor is always clipped to the window rectangle, even if part of *prclClip* is outside it.

The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) can also be used, if supported by the language.

rc ([BOOL](#)) - returns
Success indicator.

TRUE
Successful completion

FALSE
Error occurred.

WinCreateCursor - Remarks

The cursor is used to indicate the position of text input. It is initially hidden and must be made visible using the [WinShowCursor](#) function.

This function destroys any existing cursor, as it is confusing to the user if two cursors are visible at any one time. An application creates and displays a cursor when it has the input focus, or is the active window. Creating a cursor at any other time can stop the cursor from flashing in another window. Similarly, when the application loses the input focus or becomes inactive, it destroys its cursor using the [WinDestroyCursor](#) function.

The cursor width is generally specified as 0 (nominal border width is used). This is preferable to a value of 1, for example, as such a fine width is almost invisible on a high-resolution device.

When *ulrgf* is set to CURSOR_FLASH, TID_CURSOR timer is created.

WinCreateCursor - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

PMERR_INVALID_FLAG (0x1019)
An invalid bit was set for a parameter. Use constants defined by PM for options, and do not set any reserved bits.

WinCreateDlg

WinCreateDlg - Syntax

This function creates a dialog window.

```
#define INCL_WINDIALOGS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwndParent;    /* Parent-window handle of the created dialog window. */
HWND      hwndOwner;     /* Requested owner-window handle of the created dialog window. */
PFNWND    pfnDlgProc;    /* Dialog procedure for the created dialog window. */
PDLGTEMPLATE pdlgt;      /* Dialog template. */
PVOID     pCreateParams; /* Pointer to application-defined data area. */
HWND      hwndDlg;       /* Dialog-window handle. */

hwndDlg = WinCreateDlg(hwndParent, hwndOwner,
                      pfnDlgProc, pdlgt, pCreateParams);
```

WinCreateDlg Parameter - hwndParent

hwndParent ([HWND](#)) - input
Parent-window handle of the created dialog window.

HWND_DESKTOP	The desktop window
HWND_OBJECT	Object window
Other	Specified window.

WinCreateDlg Parameter - hwndOwner

hwndOwner ([HWND](#)) - input
Requested owner-window handle of the created dialog window.

The actual owner window is calculated using the algorithm specified in the description of the [WinLoadDlg](#) function.

WinCreateDlg Parameter - pfnDlgProc

pfnDlgProc ([PFNWP](#)) - input
Dialog procedure for the created dialog window.

WinCreateDlg Parameter - pDlg

pDlg ([PDLGTEMPLATE](#)) - input
Dialog template.

WinCreateDlg Parameter - pCreateParams

pCreateParams ([PVOID](#)) - input
Pointer to application-defined data area.

This is passed to the dialog procedure in the [WM_INITDLG](#) message.

This parameter **MUST** be a pointer rather than a long.

WinCreateDlg Return Value - hwndDlg

hwndDlg ([HWND](#)) - returns
Dialog-window handle.

NULLHANDLE	Dialog window not created
Other	Dialog-window handle.

WinCreateDlg - Parameters

hwndParent ([HWND](#)) - input
Parent-window handle of the created dialog window.

HWND_DESKTOP	The desktop window
HWND_OBJECT	Object window
Other	Specified window.

hwndOwner ([HWND](#)) - input
Requested owner-window handle of the created dialog window.

The actual owner window is calculated using the algorithm specified in the description of the [WinLoadDlg](#) function.

pfnDlgProc ([PFNWP](#)) - input
Dialog procedure for the created dialog window.

pdlg ([PDLGTEMPLATE](#)) - input
Dialog template.

pCreateParams ([PVOID](#)) - input
Pointer to application-defined data area.

This is passed to the dialog procedure in the [WM_INITDLG](#) message.

This parameter MUST be a pointer rather than a long.

hwndDlg ([HWND](#)) - returns
Dialog-window handle.

NULLHANDLE	Dialog window not created
Other	Dialog-window handle.

WinCreateDlg - Remarks

This function is identical to the [WinLoadDlg](#) call except that it creates a dialog window from *pdlg* in memory, rather than a dialog template in a resource file.

This function should not be used while the pointing device capture is set (see [WinSetCapture](#)).

WinCreateDlg - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

PMERR_INVALID_INTEGER_ATOM (0x1016)
The specified atom is not a valid integer atom.

PMERR_INVALID_ATOM_NAME (0x1015)
An invalid atom name string was passed.

PMERR_ATOM_NAME_NOT_FOUND (0x1017)
The specified atom name is not in the atom table.

WinCreateDlg - Example Code

This example loads a dialog template from the application's resources and uses the template with the WinCreateDlg function to create a dialog window. This example is identical to calling the WinLoadDlg function, but gives the application the advantage of reviewing and modifying the dialog template before creating the dialog window.

```
#define INCL_WINDIALOGS          /* Window Dialog Mgr Functions */
#define INCL_DOSRESOURCES        /* OS/2 Resource functions */
#include <os2.h>

PFNWP    MyDlgProc;
#define   ID_DIALOG  1

PDLGTEMPLATE pdlgt;          /* dialog template */

DosGetResource(0L, RT_DIALOG, ID_DIALOG, (PVOID)pdlgt);

/* make any changes to dialog template here */

WinCreateDlg(HWND_DESKTOP,
    NULLHANDLE, /* owner window */
    MyDlgProc,  /* address of dialog procedure */
    pdlgt,      /* address of dialog structure */
    NULL);      /* application-specific data */
```

WinCreateFrameControls

WinCreateFrameControls - Syntax

This function creates the standard frame controls for a specified window.

```
#define INCL_WINFRAMEMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwndFrame; /* Frame-window handle. */
PFRAMECDATA pfcdata; /* Frame-control data. */
PSZ       pszTitle; /* Title string. */
BOOL      rc; /* Success indicator. */

rc = WinCreateFrameControls(hwndFrame, pfcdata,
                           pszTitle);
```

WinCreateFrameControls Parameter - hwndFrame

hwndFrame (**HWND**) - input
Frame-window handle.

Becomes the parent and owner window of all the frame controls that are created:

HWND_DESKTOP	The desktop window
HWND_OBJECT	Object window
Other	Specified window.

WinCreateFrameControls Parameter - pfcdata

pfcdata (**PFRAMECDATA**) - input
Frame-control data.

This includes a combination of frame creation flags (FCF_*), that specifies which frame controls are to be created. For further information, see

WinCreateFrameControls Parameter - pszTitle

pszTitle (**PSZ**) - input

Title string.

This parameter contains a string that is displayed in the WC_TITLEBAR control only when FCF_TITLEBAR is specified in *pfcdata*.

WinCreateFrameControls Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinCreateFrameControls - Parameters

hwndFrame (**HWND**) - input
Frame-window handle.

Becomes the parent and owner window of all the frame controls that are created:

HWND_DESKTOP	The desktop window
HWND_OBJECT	Object window
Other	Specified window.

pfcdata (**PFRAMECDATA**) - input
Frame-control data.

This includes a combination of frame creation flags (FCF_*), that specifies which frame controls are to be created. For further information, see

pszTitle (**PSZ**) - input
Title string.

This parameter contains a string that is displayed in the WC_TITLEBAR control only when FCF_TITLEBAR is specified in *pfcdata*.

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinCreateFrameControls - Remarks

This function is typically used when the standard frame controls are needed for use with a nonstandard window (such as a non WC_FRAME class).

All of the controls are created with the standard FID_* window identifiers; see

The controls are created but not formatted. Formatting must be done by setting the required positions. All controls are created with position and size set to zero and WS_VISIBLE is not set.

WinCreateFrameControls - Errors

Possible returns from `WinGetLastError`

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

PMERR_INVALID_FLAG (0x1019)
An invalid bit was set for a parameter. Use constants defined by PM for options, and do not set any reserved bits.

WinCreateHelpInstance

WinCreateHelpInstance - Syntax

This function creates an instance of the Help Manager with which to request Help Manager functions.

```

#define INCL_WINHELP /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;
PHELPINIT phinitHMIInitStructure; /* Anchor-block handle. */
HWND     hwndhelp;                /* Help Manager initialization structure. */

hwndhelp = WinCreateHelpInstance(hab, phinitHMIInitStructure);

```

WinCreateHelpInstance Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

The handle of the application anchor block returned from the [WinInitialize](#) function.

WinCreateHelpInstance Parameter - phinitHMInitStructure

phinitHMInitStructure ([PHELPINIT](#)) - in/out
Help Manager initialization structure.

WinCreateHelpInstance Return Value - hwndhelp

hwndhelp ([HWND](#)) - returns
Help Manager handle.

NULLHANDLE	Error occurred
Other	Help Manager handle.

WinCreateHelpInstance - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

The handle of the application anchor block returned from the [WinInitialize](#) function.

phinitHMInitStructure ([PHELPINIT](#)) - in/out
Help Manager initialization structure.

hwndhelp ([HWND](#)) - returns
Help Manager handle.

NULLHANDLE	Error occurred
Other	Help Manager handle.

WinCreateHelpInstance - Remarks

If an error occurs, it is in the parameter of the [HELPINIT](#) structure.

WinCreateHelpInstance - Example Code

This example shows a typical main function for an application which uses help. Following creation of the main application window the Help Manager is initialized and associated with the window. The help table is defined in the application's resources. When the window is destroyed, terminating the application, the help instance is also destroyed.

```
#define INCL=_WIN
#include <os2.h>

#define IDHT_APPLICATION      100      /* id of HELP TABLE in resource file
*/

main( int argc, char *argv[], char *envp[] )
{
    HAB hab = WinInitialize( 0 );
    HMQ hmq = WinCreateMsgQueue( hab, 0 );
    HWND hwnd;
    HWND hwndClient;
    HWND hwndHelp;
    QMSG qmsg;
    ULONG flStyle;
    HELPINIT helpinit;

    /* Setup the help initialization structure */
    helpinit.cb = sizeof( HELPINIT );
    helpinit.ulReturnCode = 0L;
    helpinit.pszTutorialName = (PSZ)NULL;
    /* Help table in application resource */
    helpinit.phtHelpTable = (PHELPTABLE)MAKEULONG( IDHT_APPLICATION, 0xffff );
    helpinit.hmodHelpTableModule = NULLHANDLE;
    /* Default action bar and accelerators */
    helpinit.hmodAccelActionBarModule = NULLHANDLE;
    helpinit.idAccelTable = 0;
    helpinit.idActionBar = 0;
    helpinit.pszHelpWindowTitle = "APPNAME HELP";
    helpinit.fShowPanelId = CMIC_SHOW_PANEL_ID;
    helpinit.pszHelpLibraryName = "APPNAME.HLP";

    /* Register the class */
    if( WinRegisterClass( ... ) )
    {
        /* create the main window */
        flStyle = FCF_STANDARD;
        hwnd = WinCreateStdWindow( ... );

        if( hwnd )
        {
            /* Create and associate the help instance */
            hwndHelp = WinCreateHelpInstance( hab, &helpinit );

            if( hwndHelp && WinAssociateHelpInstance( hwndHelp, hwnd ) )
            {
                /* Process messages */
                while( WinGetMsg( hab, &qmsg, NULLHANDLE, 0, 0 ) )
```

```

        {
            WinDispatchMsg( hab, &qmsg );
        } /* endwhile */
    }

    /* Remove help instance - note: add */
    /* WinAssociateHelpInstance( NULLHANDLE, hwnd ); */
    /* to WM_DESTROY processing to remove the association. */
    WinDestroyHelpInstance( hwndHelp );
}

/* finish the cleanup and exit */
WinDestroyMsgQueue( hmq );
WinTerminate( hab );
}

```

WinCreateHelpTable

WinCreateHelpTable - Syntax

This function is used to identify or change the help table.

```

#define INCL_WINHELP /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwndHelpInstance; /* Handle of an instance of the Help Manager. */
PHELPTEXT phtHelpTable;     /* Help table allocated by the application. */
BOOL      rc;                /* Success indicator. */

rc = WinCreateHelpTable(hwndHelpInstance,
                        phtHelpTable);

```

WinCreateHelpTable Parameter - hwndHelpInstance

hwndHelpInstance ([HWND](#)) - input
Handle of an instance of the Help Manager.

This is the handle returned by the [WinCreateHelpInstance](#) call.

WinCreateHelpTable Parameter - phtHelpTable

phtHelpTable ([PHELP_TABLE](#)) - input
Help table allocated by the application.

WinCreateHelpTable Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinCreateHelpTable - Parameters

hwndHelpInstance ([HWND](#)) - input
Handle of an instance of the Help Manager.

This is the handle returned by the [WinCreateHelpInstance](#) call.

phtHelpTable ([PHELP_TABLE](#)) - input
Help table allocated by the application.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinCreateHelpTable - Remarks

This function corresponds to the [HM_CREATE_HELP_TABLE](#) message that identifies a help table that is in memory.

WinCreateHelpTable - Example Code

This example creates a help table in memory and passes the table to the Help Manager via WinCreateHelpTable. The help instance must have been created by WinCreateHelpInstance.

```
#define INCL_WINHELP
#include <os2.h>

/* DEFINES for window id's, menu items, controls, panels, etc. should */
/* be inserted here or in additional include files. */

/* Subtable for the main window's help */
HELPSUBTABLE phtMainTable[] = { 2, /* Length of each entry */
/* Fill in one line for each menu item */
IDM_FILE, PANELID_FILEMENU,
IDM_FILENEW, PANELID_FILENEW,
IDM_FILEOPEN, PANELID_FILEOPEN,
IDM_FILESAVE, PANELID_FILESAVE,
IDM_FILESAVEAS, PANELID_FILESAVEAS,
IDM_FILEEXIT, PANELID_FILEEXIT };

/* Subtable for the dialog window's help */
HELPSUBTABLE phtDlgTable[] = { 2, /* Length of each entry */
/* Fill in one line for each control */
IDC_EDITFLD, PANELID_DLGEDITFLD,
IDC_OK, PANELID_DLGOK,
IDC_CANCEL, PANELID_DLGCANCEL,
IDC_HELP, PANELID_HELP };

/* Help table for the applications context sensitive help */
HELPTABLE phtHelpTable[] = { WINDOWID_MAIN, phtMainTable,
PANELID_MAINEXT,
WINDOWID_DLG, phtDlgTable, PANELID_DLGEEXT,
0, NULL, 0 };

BOOL CreateHelpTable( HWND hWnd )
{
    BOOL bSuccess = FALSE;
    HWND hwndHelp;

    /* Get the associated help instance */
    hwndHelp = WinQueryHelpInstance( hWnd );

    if( hwndHelp )
    {
        /* Pass address of help table to the Help Manager */
    }
}
```

```

        bSuccess = WinCreateHelpTable( hwndHelp, phtHelpTable );
    }

    /* return success indicator */
    return bSuccess;
}

```

WinCreateMenu

WinCreateMenu - Syntax

This function creates a menu window from the menu template.

```

#define INCL_WINMENUS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwndParent; /* Owner- and parent-window handle of the created menu window. */
PVOID     lpmt;       /* Menu template in binary format. */
HWND      hwndMenu;   /* Menu-window handle. */

hwndMenu = WinCreateMenu(hwndParent, lpmt);

```

WinCreateMenu Parameter - hwndParent

hwndParent ([HWND](#)) - input

Owner- and parent-window handle of the created menu window.

If this is `HWND_OBJECT` or a window handle returned by the [WinQueryObjectWindow](#) call, the menu window is created as an object window.

`HWND_DESKTOP`
The desktop window

HWND_OBJECT Object window
Other Specified window.

WinCreateMenu Parameter - lpmt

lpmt ([PVOID](#)) - input
Menu template in binary format.

WinCreateMenu Return Value - hwndMenu

hwndMenu ([HWND](#)) - returns
Menu-window handle.

WinCreateMenu - Parameters

hwndParent ([HWND](#)) - input
Owner- and parent-window handle of the created menu window.

If this is HWND_OBJECT or a window handle returned by the [WinQueryObjectWindow](#) call, the menu window is created as an object window.

HWND_DESKTOP The desktop window
HWND_OBJECT Object window
Other Specified window.

lpmt ([PVOID](#)) - input
Menu template in binary format.

hwndMenu ([HWND](#)) - returns
Menu-window handle.

WinCreateMenu - Remarks

The menu window is created with an identity of FID_MENU.

WinCreateMenu - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinCreateMenu - Related Functions

WinCreateMsgQueue

WinCreateMsgQueue - Syntax

This function creates a message queue.

```
#define INCL_WINMESSAGEGR /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
LONG     lQueueSize;   /* Maximum queue size. */
HMQ      hmq;          /* Message-queue handle. */

hmq = WinCreateMsgQueue(hab, lQueueSize);
```

WinCreateMsgQueue Parameter - hab

hab (**HAB**) - input
Anchor-block handle.

WinCreateMsgQueue Parameter - lQueueSize

lQueueSize (**LONG**) - input
Maximum queue size.

This parameter is ignored for **versions higher than version 3** of the OS/2 operating system. The *lQueueSize* parameter is dynamically allocated. The maximum queue size should be set to zero.

For **version 3 and lower** of the OS/2 operating system, this parameter is the maximum number of messages that can be queued.

0 Use the system default queue size which is 10 messages.

Other Maximum queue size.

WinCreateMsgQueue Return Value - hmq

hmq (**HMQ**) - returns
Message-queue handle.

NULLHANDLE Queue cannot be created.

Other Message-queue handle.

WinCreateMsgQueue - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

IQueueSize ([LONG](#)) - input
Maximum queue size.

This parameter is ignored for **versions higher than version 3** of the OS/2 operating system. The *IQueueSize* parameter is dynamically allocated. The maximum queue size should be set to zero.

For **version 3 and lower** of the OS/2 operating system, this parameter is the maximum number of messages that can be queued.

0 Use the system default queue size which is 10 messages.

Other Maximum queue size.

hmq ([HMQ](#)) - returns
Message-queue handle.

NULLHANDLE Queue cannot be created.

Other Message-queue handle.

WinCreateMsgQueue - Remarks

Most PM calls require a message queue. WinCreateMsgQueue must be issued after the [WinInitialize](#) function, but before any other PM calls are invoked. It must be issued only once per thread.

WinCreateMsgQueue - Errors

Possible returns from [WinGetLastError](#)

PMERR_HEAP_MAX_SIZE_REACHED (0x1012)
The heap has reached its maximum size (64KB), and cannot be increased.

PMERR_HEAP_OUT_OF_MEMORY (0x1011)
An attempt to increase the size of the heap failed.

PMERR_QUEUE_TOO_LARGE (0x1018)
An attempt to create a message queue has failed because the value specified for the size of the message queue is too large.

PMERR_RESOURCE_NOT_FOUND (0x100A)
The specified resource identity could not be found.

PMERR_NOT_IN_A_PM_SESSION (0x1051)
An attempt was made to access function that is only available from PM programs from a non-PM session.

PMERR_MSG_QUEUE_ALREADY_EXISTS (0x1052)
An attempt to create a message queue for a thread failed because a message queue already exists for the calling thread.

WinCreateObject

WinCreateObject - Syntax

This function creates an instance of object class *pszClassName*, with title *pszTitle*, and places the icon and title in the location referred to by *pszLocation*.

```
#define INCL_WINWORKPLACE
#include <os2.h>

PSZ      pszClassName;    /* Pointer to class name. */
PSZ      pszTitle;        /* Pointer to initial title of object. */
PSZ      pszSetupString;  /* Pointer to setup string. */
PSZ      pszLocation;     /* Folder location. */
ULONG    ulFlags;         /* Creation flags. */
HOBJECT  rc;              /* Handle to the created object. */

rc = WinCreateObject(pszClassName, pszTitle,
    pszSetupString, pszLocation, ulFlags);
```

WinCreateObject Parameter - pszClassName

pszClassName ([PSZ](#)) - input
Pointer to class name.

A pointer to a zero-terminated string which contains the name of the class of which this object is a member.

WinCreateObject Parameter - pszTitle

pszTitle ([PSZ](#)) - input
Pointer to initial title of object.

A pointer to a zero-terminated string which contains the initial title of the object as it is to appear when displayed on the user interface underneath an icon or on the title bar of an open object.

WinCreateObject Parameter - pszSetupString

pszSetupString ([PSZ](#)) - input
Pointer to setup string.

See the Workplace class definition for WPLaunchPad for a table of setup strings used to customize the Toolbar.

WinCreateObject Parameter - pszLocation

pszLocation ([PSZ](#)) - input
Folder location.

This value can be in any of the following formats:

- Predefined object ids of system folders.

"<WP_NOWHERE>"	The hidden folder.
"<LOCATION_DESKTOP>"	The currently active desktop.
"<WP_OS2SYS>"	The System folder.
"<WP_TEMPS>"	The Templates folder.
"<WP_CONFIG>"	The System Setup folder.
"<WP_START>"	The Startup folder.
"<WP_INFO>"	The Information folder.
"<WP_DRIVES>"	The Drives folder.
- Real name specified as a fully qualified path name.

WinCreateObject Parameter - ulFlags

ulFlags ([ULONG](#)) - input
Creation flags.

This parameter can have one of the following values:

- | | |
|--------------------|--|
| CO_FAILIFEXISTS | No object will be created if an object with the given object ID already exists. This is the default. |
| CO_REPLACEIFEXISTS | If an object with the given ID already exists, the existing object should be replaced. |
| CO_UPDATEIFEXISTS | If an object with the given ID already exists, the existing object should be updated with the new information. |

WinCreateObject Return Value - rc

rc ([HOBJECT](#)) - returns
Handle to the created object.

NULLHANDLE
Error occurred.

Other

A handle to the object created. This handle is persistent and can be used for the [WinSetObjectData](#) and [WinDestroyObject](#) function calls.

WinCreateObject - Parameters

pszClassName ([PSZ](#)) - input
Pointer to class name.

A pointer to a zero-terminated string which contains the name of the class of which this object is a member.

pszTitle ([PSZ](#)) - input
Pointer to initial title of object.

A pointer to a zero-terminated string which contains the initial title of the object as it is to appear when displayed on the user interface underneath an icon or on the title bar of an open object.

pszSetupString ([PSZ](#)) - input
Pointer to setup string.

See the Workplace class definition for WPLaunchPad for a table of setup strings used to customize the Toolbar.

pszLocation ([PSZ](#)) - input
Folder location.

This value can be in any of the following formats:

- Predefined object ids of system folders.

"<WP_NOWHERE>"
"<LOCATION_DESKTOP>"
"<WP_OS2SYS>"
"<WP_TEMP>"
"<WP_CONFIG>"
"<WP_START>"
"<WP_INFO>"
"<WP_DRIVES>"

The hidden folder.
The currently active desktop.
The System folder.
The Templates folder.
The System Setup folder.
The Startup folder.
The Information folder.
The Drives folder.

- Real name specified as a fully qualified path name.

ulFlags ([ULONG](#)) - input
Creation flags.

This parameter can have one of the following values:

CO_FAILIFEXISTS

No object will be created if an object with the given object ID already exists. This is the default.

CO_REPLACEIFEXISTS

If an object with the given ID already exists, the existing object should be replaced.

CO_UPDATEIFEXISTS

If an object with the given ID already exists, the existing object should be updated with the new information.

rc ([HOBJECT](#)) - returns
Handle to the created object.

NULLHANDLE

Error occurred.

Other

A handle to the object created. This handle is persistent and can be used for the [WinSetObjectData](#) and [WinDestroyObject](#) function calls.

WinCreateObject - Remarks

The *pszSetupString* contains a series of "keyname=value" pairs, that change the behavior of the object. "keynames" are separated by semicolons, and "values" are separated by commas.

```
"key=value;key2=value1,value2;"
```

If you want a literal comma or a literal semicolon inside one of your fields you must type the following:

^,	A literal comma.
^;	A literal semicolon.

Each object class documents the keynames and the parameters it expects to see immediately following. See the following keyname-value pairs tables:

- WPColorPalette
- WPDisk
- WPFolder
- WPFontPalette
- WPKeyboard
- WPLaunchPad
- WPPalette
- WPPrinter
- WPRPrinter
- WPProgram
- WPProgramFile
- WPSchemePalette
- WPShadow
- WPObject

Note that ALL parameters have safe defaults, so it is never necessary to pass unnecessary parameters to an object.

For more information about object classes, see the *Workplace Shell Programming Guide*.

Using [HOBJECT](#) for .INI files or files in which an application uses a rename/save/delete sequence is not supported.

WinCreatePointer

WinCreatePointer - Syntax

This function creates a pointer from a bit map.

```
#define INCL_WINPOINTERS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwndDesktop; /* Desktop-window handle or HWND_DESKTOP. */
HBITMAP   hbmPointer; /* Bit-map handle from which the pointer image is created. */
BOOL      fPointer; /* Pointer-size indicator. */
LONG      xHotspot; /* x-offset of hot spot within pointer from its lower left corner (in pels). */
LONG      yHotspot; /* y-offset of hot spot within pointer from its lower left corner (in pels). */
HPOINTER  hptr; /* Pointer handle. */

hptr = WinCreatePointer(hwndDesktop, hbmPointer,
                        fPointer, xHotspot, yHotspot);
```

WinCreatePointer Parameter - hwndDesktop

hwndDesktop ([HWND](#)) - input
Desktop-window handle or HWND_DESKTOP.

WinCreatePointer Parameter - hbmPointer

hbmPointer ([HBITMAP](#)) - input
Bit-map handle from which the pointer image is created.

The bit map must be logically divided into two sections vertically, each half representing one of the two images used as the successive drawing masks for the pointer.

For an icon, there are two bit map images. The first half is used for the AND mask and the second half is used for the XOR mask. For details of bit map formats, see

WinCreatePointer Parameter - fPointer

fPointer (BOOL) - input
Pointer-size indicator.

TRUE	The bit map should be stretched (if necessary) to the system pointer dimensions.
FALSE	The bit map should be stretched (if necessary) to the system icon dimensions.

WinCreatePointer Parameter - xHotspot

xHotspot (LONG) - input
x-offset of hot spot within pointer from its lower left corner (in pels).

WinCreatePointer Parameter - yHotspot

yHotspot (LONG) - input
y-offset of hot spot within pointer from its lower left corner (in pels).

WinCreatePointer Return Value - hptr

hptr (HPOINTER) - returns
Pointer handle.

NULLHANDLE	Error
Other	Handle of the newly created pointer.

WinCreatePointer - Parameters

hwndDesktop (HWND) - input
Desktop-window handle or HWND_DESKTOP.

hbmPointer (HBITMAP) - input
Bit-map handle from which the pointer image is created.

The bit map must be logically divided into two sections vertically, each half representing one of the two images used as the successive drawing masks for the pointer.

For an icon, there are two bit map images. The first half is used for the AND mask and the second half is used for the XOR mask. For details of bit map formats, see

fPointer ([BOOL](#)) - input
 Pointer-size indicator.

TRUE The bit map should be stretched (if necessary) to the system pointer dimensions.

FALSE The bit map should be stretched (if necessary) to the system icon dimensions.

xHotspot ([LONG](#)) - input
 x-offset of hot spot within pointer from its lower left corner (in pels).

yHotspot ([LONG](#)) - input
 y-offset of hot spot within pointer from its lower left corner (in pels).

hptr ([HPOINTER](#)) - returns
 Pointer handle.

NULLHANDLE Error

Other Handle of the newly created pointer.

WinCreatePointer - Remarks

A pointer can be created either as a true pointer (at pointer size), or as an icon pointer (at icon size). The latter is useful when using icons as direct-manipulation objects that the user can "pick up" and move about the screen as a means of performing some operation.

See also [WinCreatePointerIndirect](#).

This function makes copies of the supplied bit maps.

WinCreatePointer - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
 An invalid window handle was specified.

PMERR_HBITMAP_BUSY (0x2032)
 An internal bit map busy error was detected. The bit map was locked by one thread during an attempt to access it from another thread.

WinCreatePointer - Example Code

This example creates a pointer from a bit map during the creation of the window (WM_CREATE). The bit map (id IDP_BITMAP in the EXE file) is loaded via GpiLoadBitmap.

```
#define INCL_WINPOINTERS          /* Window Pointer Functions */
#define INCL_GPIBITMAPS          /* Graphics bit map Functions */
#include <os2.h>

HPS    hps;          /* presentation-space handle */
HWND   hwnd;         /* window handle */
HPOINTER hptr;       /* bit-map pointer handle */
HBITMAP hbm;         /* bit-map handle */

case WM_CREATE:
    hps = WinBeginPaint(hwnd, NULLHANDLE, NULL);
    hbm = GpiLoadBitmap(hps, 0L, IDP_BITMAP, 64L, 64L);
    WinEndPaint(hps);

    hptr = WinCreatePointer(HWND_DESKTOP, hbm,
                           TRUE, /* use true (system) pointer */
                           0, 0); /* hot spot offset (0,0) */
```

WinCreatePointerIndirect

WinCreatePointerIndirect - Syntax

This function creates a colored pointer or icon from a bit map.

```
#define INCL_WINPOINTERS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwndDesktop; /* Desktop-window handle or HWND_DESKTOP. */
PPOINTERINFO pptri; /* Pointer information structure. */
HPOINTER  hptr; /* Pointer handle. */

hptr = WinCreatePointerIndirect(hwndDesktop,
                                pptri);
```

WinCreatePointerIndirect Parameter - hwndDesktop

hwndDesktop ([HWND](#)) - input
Desktop-window handle or HWND_DESKTOP.

WinCreatePointerIndirect Parameter - pptri

pptri ([PPOINTERINFO](#)) - input
Pointer information structure.

The fields in this structure must be set before the call is made:

- *fPointer* is set to TRUE if a pointer is being created, or to FALSE if an icon is being created.
- *xHotSpot* *yHotSpot* are set to the relative position in the icon or pointer that is associated with the mouse position.
- *hbmPointer* is a bit map that specifies the AND and XOR masks, as used for black and white pointers and icons.
- *hbmColor* is a color bit map that describes the color content of the pointer or icon.

It is an error if *hbmPointer* is NULLHANDLE. Also, the width of *hbmPointer* must be the same as that of *hbmColor* and the height of *hbmPointer* must be double that of *hbmColor* (to allow for both the AND and the XOR mask).

WinCreatePointerIndirect Return Value - hptr

hptr ([HPOINTER](#)) - returns
Pointer handle.

NULLHANDLE	Error
Other	Handle of the newly created pointer or icon.

WinCreatePointerIndirect - Parameters

hWndDesktop ([HWND](#)) - input
Desktop-window handle or HWND_DESKTOP.

pptri ([PPOINTERINFO](#)) - input
Pointer information structure.

The fields in this structure must be set before the call is made:

- *fPointer* is set to TRUE if a pointer is being created, or to FALSE if an icon is being created.
- *xHotSpot* *yHotSpot* are set to the relative position in the icon or pointer that is associated with the mouse position.
- *hbmPointer* is a bit map that specifies the AND and XOR masks, as used for black and white pointers and icons.
- *hbmColor* is a color bit map that describes the color content of the pointer or icon.

It is an error if *hbmPointer* is NULLHANDLE. Also, the width of *hbmPointer* must be the same as that of *hbmColor* and the height of *hbmPointer* must be double that of *hbmColor* (to allow for both the AND and the XOR mask).

hptr ([HPOINTER](#)) - returns
Pointer handle.

NULLHANDLE

Error

Other

Handle of the newly created pointer or icon.

WinCreatePointerIndirect - Remarks

A pointer can be created either as a true pointer (at pointer size), or as an icon pointer (at icon size). The latter is useful when using icons as direct-manipulation objects that the user can "pick up" and move about the screen as a means of performing some operation (see also [WinCreatePointer](#)).

This function makes copies of the supplied bit maps.

WinCreatePointerIndirect - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

PMERR_HBITMAP_BUSY (0x2032)
An internal bit map busy error was detected. The bit map was locked by one thread during an attempt to access it from another thread.

WinCreatePointerIndirect - Example Code

This example creates a colored pointer from a bit map during the creation of the window (WM_CREATE). The pointer bit map (id IDP_BITMAPPTR in the EXE) and color bit map (id IDP_BITMAPCLR in the EXE file) are loaded via GpiLoadBitmap.

```
#define INCL_WINPOINTERS          /* Window Pointer Functions      */
#define INCL_GPIBITMAPS          /* Graphics bit map Functions  */
#include <os2.h>

HPS    hps;                      /* presentation-space handle    */
HWND   hwnd;                    /* window handle                */
HPOINTER hptr;                  /* bit-map pointer handle       */
HBITMAP hbmPointer;             /* bit-map handle (AND/XOR)     */
HBITMAP hbmColor;              /* bit-map handle (color)       */
POINTERINFO pptriPointerInfo; /* pointer info structure        */

case WM_CREATE:
    hps = WinBeginPaint(hwnd, NULLHANDLE, NULL);
    /* load pointer bit map */
    hbmPointer = GpiLoadBitmap(hps, NULLHANDLE, IDP_BITMAPPTR, 64L, 128L);
    /* load color bit map */
    hbmColor = GpiLoadBitmap(hps, NULLHANDLE, IDP_BITMAPCLR, 64L, 64L);
    WinEndPaint(hps);

    /* initialize POINTERINFO structure */
    pptriPointerInfo.fPointer = TRUE; /* creating pointer */
    pptriPointerInfo.xHotspot = 0; /* x coordinate of hotspot */
    pptriPointerInfo.yHotspot = 0; /* y coordinate of hotspot */
    pptriPointerInfo.hbmPointer = hbmPointer;
    pptriPointerInfo.hbmColor = hbmColor;

    hptr = WinCreatePointerIndirect(HWND_DESKTOP,
                                    &pptriPointerInfo);
```

WinCreateShadow

WinCreateShadow - Syntax

This function is specific to OS/2 Version 3.0 or higher.

This function creates a shadow of an object and places it in a specified location.

```
#define INCL_WINWORKPLACE
#include <os2.h>

HOBJECT    hObjectofObject; /* Handle of the object from which the shadow is to be created. */
HOBJECT    hObjectofDest;  /* Handle of the folder into which hObjectofObject is to be placed. */
ULONG      ulReserved;     /* Reserved value; must be 0. */
HOBJECT     rc;             /* Handle of the newly created shadow object. */

rc = WinCreateShadow(hObjectofObject, hObjectofDest,
                    ulReserved);
```

WinCreateShadow Parameter - hObjectofObject

hObjectofObject (**HOBJECT**) - input
Handle of the object from which the shadow is to be created.

WinCreateShadow Parameter - hObjectofDest

hObjectofDest (**HOBJECT**) - input
Handle of the folder into which *hObjectofObject* is to be placed.

WinCreateShadow Parameter - ulReserved

ulReserved (**ULONG**) - input
Reserved value; must be 0.

WinCreateShadow Return Value - rc

rc ([HOBJECT](#)) - returns
Handle of the newly created shadow object.

A return value of NULLHANDLE indicates that either *hObjectofDest* is NULLHANDLE or an object with the same name as *hObjectofObject* exists in the destination folder.

WinCreateShadow - Parameters

hObjectofObject ([HOBJECT](#)) - input
Handle of the object from which the shadow is to be created.

hObjectofDest ([HOBJECT](#)) - input
Handle of the folder into which *hObjectofObject* is to be placed.

ulReserved ([ULONG](#)) - input
Reserved value; must be 0.

rc ([HOBJECT](#)) - returns
Handle of the newly created shadow object.

A return value of NULLHANDLE indicates that either *hObjectofDest* is NULLHANDLE or an object with the same name as *hObjectofObject* exists in the destination folder.

WinCreateShadow - Remarks

Using [HOBJECT](#) for .INI files or files in which an application uses a rename/save/delete sequence is not supported. Its REXX counterpart is SysCreateShadowObject.

WinCreateStdWindow

WinCreateStdWindow - Syntax

This function creates a standard window.

```
#define INCL_WINFRAMEMGR /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HWND      hwndParent;      /* Parent-window handle. */
ULONG     flStyle;         /* Frame-window style. */
PULONG    pflCreateFlags;  /* Frame-creation flags. */
PSZ       pszClassClient;  /* Client-window class name. */
PSZ       pszTitle;        /* Title-bar text. */
ULONG     flStyleClient;   /* Client-window style. */
HMODULE    Resource;       /* Resource identifier. */
ULONG     ulId;            /* Frame-window identifier. */
PHWND     phwndClient;     /* Client-window handle. */
HWND      hwndFrame;       /* Frame-window handle. */

hwndFrame = WinCreateStdWindow(hwndParent,
                               flStyle, pflCreateFlags, pszClassClient,
                               pszTitle, flStyleClient, Resource,
                               ulId, phwndClient);
```

WinCreateStdWindow Parameter - hwndParent

hwndParent ([HWND](#)) - input
Parent-window handle.

If this parameter is a window handle returned from the [WinQueryDesktopWindow](#) function, or is `HWND_DESKTOP`, a main window is created.

If *hwndParent* is a window handle returned from [WinQueryObjectWindow](#), or is `HWND_OBJECT`, an object window is created.

WinCreateStdWindow Parameter - flStyle

flStyle ([ULONG](#)) - input
Frame-window style.

This is a combination of any of the `WS_*` styles frame styles.

The interpretation of the parameters is affected by the use of all the styles, except for WS_MINIMIZED and WS_MAXIMIZED. These two styles are ignored if they are specified.

WinCreateStdWindow Parameter - pflCreateFlags

pflCreateFlags ([PULONG](#)) - input
Frame-creation flags.

This contains a combination of any of the FCF_* flags. The interpretation of the parameters is affected by the use of these flags; see

WinCreateStdWindow Parameter - pszClassClient

pszClassClient ([PSZ](#)) - input
Client-window class name.

If *pszClassClient* is not a zero-length string, a client window of style *flStyleClient* and class *pszClassClient* is created. *pszClassClient* is either an application specified name as defined by [WinRegisterClass](#) or the name of a preregistered WC_* class; see Preregistered class names are of the form "#nnnnn", where nnnnn is 1 through 5 digits corresponding to the value of the WC_* class name constant.

If *pszClassClient* is NULL, no client area is created.

This parameter can also be specified directly as a WC_* constant.

WinCreateStdWindow Parameter - pszTitle

pszTitle ([PSZ](#)) - input
Title-bar text.

This is ignored if FCF_TITLEBAR (or FCF_STANDARD) is not specified in *pflCreateFlags*.

WinCreateStdWindow Parameter - flStyleClient

flStyleClient ([ULONG](#)) - input
Client-window style.

This is ignored if *pszClassClient* is a zero-length string.

WinCreateStdWindow Parameter - Resource

Resource ([HMODULE](#)) - input
Resource identifier.

This is ignored unless FCF_MENU, FCF_STANDARD, FCF_ACCELTABLE, or FCF_ICON is specified.

NULLHANDLE

Resource definitions are contained in the application .EXE file.

Other

The module handle returned by the DosLoadModule or DosQueryModuleHandle call of the Dynamic Link Library (DLL) containing the resource definitions.

WinCreateStdWindow Parameter - ulld

ulld ([ULONG](#)) - input
Frame-window identifier.

The identifier within the resource definition of the required resource.

It is the responsibility of the application to ensure that all of the resources related to one frame window have the same *ulld* value. It must be greater or equal to 0 and less or equal to 0xFFFF.

WinCreateStdWindow Parameter - phwndClient

phwndClient ([PHWND](#)) - output
Client-window handle.

This is returned if a client window is created.

WinCreateStdWindow Return Value - hwndFrame

hwndFrame ([HWND](#)) - returns
Frame-window handle.

This is NULLHANDLE if no window is created.

WinCreateStdWindow - Parameters

hwndParent ([HWND](#)) - input
Parent-window handle.

If this parameter is a window handle returned from the [WinQueryDesktopWindow](#) function, or is HWND_DESKTOP, a main window is

created.

If *hwndParent* is a window handle returned from [WinQueryObjectWindow](#), or is HWND_OBJECT, an object window is created.

flStyle ([ULONG](#)) - input
Frame-window style.

This is a combination of any of the WS_* styles frame styles.

The interpretation of the parameters is affected by the use of all the styles, except for WS_MINIMIZED and WS_MAXIMIZED. These two styles are ignored if they are specified.

pflCreateFlags ([PULONG](#)) - input
Frame-creation flags.

This contains a combination of any of the FCF_* flags. The interpretation of the parameters is affected by the use of these flags; see

pszClassClient ([PSZ](#)) - input
Client-window class name.

If *pszClassClient* is not a zero-length string, a client window of style *flStyleClient* and class *pszClassClient* is created. *pszClassClient* is either an application specified name as defined by [WinRegisterClass](#) or the name of a preregistered WC_* class; see Preregistered class names are of the form "#nnnnn", where nnnnn is 1 through 5 digits corresponding to the value of the WC_* class name constant.

If *pszClassClient* is NULL, no client area is created.

This parameter can also be specified directly as a WC_* constant.

pszTitle ([PSZ](#)) - input
Title-bar text.

This is ignored if FCF_TITLEBAR (or FCF_STANDARD) is not specified in *pflCreateFlags*.

flStyleClient ([ULONG](#)) - input
Client-window style.

This is ignored if *pszClassClient* is a zero-length string.

Resource ([HMODULE](#)) - input
Resource identifier.

This is ignored unless FCF_MENU, FCF_STANDARD, FCF_ACCELTABLE, or FCF_ICON is specified.

NULLHANDLE

Resource definitions are contained in the application .EXE file.

Other

The module handle returned by the DosLoadModule or DosQueryModuleHandle call of the Dynamic Link Library (DLL) containing the resource definitions.

ulld ([ULONG](#)) - input
Frame-window identifier.

The identifier within the resource definition of the required resource.

It is the responsibility of the application to ensure that all of the resources related to one frame window have the same *ulld* value. It must be greater or equal to 0 and less or equal to 0xFFFF.

phwndClient ([PHWND](#)) - output
Client-window handle.

This is returned if a client window is created.

hwndFrame ([HWND](#)) - returns
Frame-window handle.

This is NULLHANDLE if no window is created.

WinCreateStdWindow - Remarks

The window is created with zero width and depth and positioned at the bottom left of the *hwndParent*, unless FCF_SHELLPOSITION is specified, in which case the size and position are set by the shell. The window can be positioned and sized by use of [WinSetWindowPos](#).

If WS_VISIBLE is set, the frame window is created visible. It is recommended that standard windows that are not main windows are created with WS_VISIBLE not set.

hwndFrame is the window handle of the frame window, that is, the window of class WC_FRAME, and has a parent of *hwndParent*.

The frame window is created with identity *uId*, all the component windows, known as the frame controls, have the standard window identifiers FID_*; see The identifier FID_CLIENT is used for the client area of the window.

It may be necessary to change the *uId* of the frame window after it has been created, so that another frame window can be created with the same resource tables, and still maintain distinct window identities. This can be achieved with the [WinSetWindowUShort](#) call.

Some combinations of frame control flags are valid, but leave visual holes in the frame window. Specifically, if the *pflCreateFlags* parameter specifies any of FCF_SYSMENU, FCF_MINBUTTON, FCF_MAXBUTTON or FCF_MINMAX, but not FCF_TITLEBAR, the area of the top title line between the optional system menu and the minimize/maximize icons is not drawn by the default frame window procedure.

None of the following can be used with WinCreateStdWindow:

- WS_CLIPCHILDREN for the frame style
- WS_CLIPSIBLINGS for the style of the client window or any of the frame control windows
- CS_CLIPSIBLINGS for the class style of the window.

If any of the above are specified, the window is not redrawn correctly. Any style can be used for the children of the client. If it really is required that a client or a frame control is CLIPSIBLINGS, the application must ensure that it is in front of the client and all the other frame controls, for it to be drawn.

WinCreateStdWindow - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

PMERR_INVALID_FLAG (0x1019)
An invalid bit was set for a parameter. Use constants defined by PM for options, and do not set any reserved bits.

PMERR_INVALID_INTEGER_ATOM (0x1016)
The specified atom is not a valid integer atom.

PMERR_INVALID_ATOM_NAME (0x1015)
An invalid atom name string was passed.

PMERR_ATOM_NAME_NOT_FOUND (0x1017)
The specified atom name is not in the atom table.

WinCreateStdWindow - Example Code

This example shows a typical initialization function for a window. The function first registers the window class, then calls WinCreateStdWindow to create a standard window and returns immediately if the function fails. Otherwise, it continues on to do other initialization processing. Note: The FCF_STANDARD constant can only be used if you have all the resources in defines. If you use this constant without an accelerator table for example, the function will fail.

```
#define INCL_WINFRAMEMGR          /* Window Frame Functions */
#include <os2.h>
#define IDM_RESOURCE 1
HAB hab;                          /* Anchor-block handle */
CHAR szClassName[] = "Generic"; /* window class name */
HWND hwndClient;                 /* handle to the client */
HWND hwndFrame;                 /* handle to the frame */
PFNWP GenericWndProc;
BOOL GenericInit()
{
    ULONG flStyle;

    flStyle = FCF_STANDARD;
    if (!WinRegisterClass(hab, szClassName, GenericWndProc, 0L, 0))
        return (FALSE);

    hwndFrame = WinCreateStdWindow(HWND_DESKTOP,
        0L, /* frame-window style */
        &flStyle, /* window style */
        szClassName, /* class name */
        "Generic Application", /* window title */
        0L, /* default client style */
        NULLHANDLE, /* resource in executable file */
        IDM_RESOURCE, /* resource id */
        &hwndClient); /* receives client window handle */

    if (!hwndFrame)
        return (FALSE);
    else {
        .
        . /* other initialization code */
        .
    }
}
```

WinCreateSwitchEntry

WinCreateSwitchEntry - Syntax

This function adds an entry to the Window List.

```
#define INCL_WINSWITCHLIST /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;           /* Anchor-block handle. */
PSWCNTRL pswctlSwitchData; /* Switch data. */
HSWITCH  hswitchSwitch; /* Handle to the newly created Window List entry. */

hswitchSwitch = WinCreateSwitchEntry(hab,
                                     pswctlSwitchData);
```

WinCreateSwitchEntry Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinCreateSwitchEntry Parameter - pswctlSwitchData

pswctlSwitchData ([PSWCNTRL](#)) - input
Switch data.

Contains information about the newly created Window List entry.

If the field of the [SWCNTRL](#) structure is NULL, the system uses the name under which the application is started. This only applies for OS/2 programs, and only for the first call to this function since the program started. Otherwise, a NULL entry name is invalid.

Leading and trailing blanks are removed from the title, which, if necessary, is also truncated to 60 characters.

If the field of the [SWCNTRL](#) structure is NULLHANDLE, the value used by the system when the program was loaded (if it has been loaded) is substituted.

If the field of the [SWCNTRL](#) structure is 0, the current process ID is used.

If the field of the [SWCNTRL](#) structure is 0, the current session ID is used.

WinCreateSwitchEntry Return Value - hswitchSwitch

hswitchSwitch ([HSWITCH](#)) - returns
Handle to the newly created Window List entry.

There is a system limit to the number of Window List entries. However, this is a large number (several hundred) and is unlikely to be reached in practice since other system limits, such as memory size, are likely to be reached first.

NULLHANDLE
Error occurred
Other
Handle to the newly created Window List entry.

WinCreateSwitchEntry - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

pswctlSwitchData ([PSWCNTRL](#)) - input
Switch data.

Contains information about the newly created Window List entry.

If the field of the [SWCNTRL](#) structure is NULL, the system uses the name under which the application is started. This only applies for OS/2 programs, and only for the first call to this function since the program started. Otherwise, a NULL entry name is invalid.

Leading and trailing blanks are removed from the title, which, if necessary, is also truncated to 60 characters.

If the field of the [SWCNTRL](#) structure is NULLHANDLE, the value used by the system when the program was loaded (if it has been loaded) is substituted.

If the field of the [SWCNTRL](#) structure is 0, the current process ID is used.

If the field of the [SWCNTRL](#) structure is 0, the current session ID is used.

hswitchSwitch ([HSWITCH](#)) - returns
Handle to the newly created Window List entry.

There is a system limit to the number of Window List entries. However, this is a large number (several hundred) and is unlikely to be reached in practice since other system limits, such as memory size, are likely to be reached first.

NULLHANDLE
Error occurred
Other
Handle to the newly created Window List entry.

WinCreateSwitchEntry - Remarks

Both this function and the [WinRemoveSwitchEntry](#) function are not required if the main window is created with the frame creation flags FCF_TASKLIST or FCF_STANDARD, as these styles automatically update the Window List when the main window is created or destroyed, or when its title changes (see also [WinAddSwitchEntry](#)).

WinCreateSwitchEntry - Errors

Possible returns from [WinGetLastError](#)

PMERR_NO_SPACE (0x1201)

The limit on the number of Window List entries has been reached with [WinAddSwitchEntry](#).

PMERR_INVALID_WINDOW (0x1206)

The window specified with a Window List call is not a valid frame window.

PMERR_INVALID_SESSION_ID (0x120B)

The specified session identifier is invalid. Either zero (for the application's own session) or a valid identifier must be specified.

WinCreateWindow

WinCreateWindow - Syntax

WinCreateWindow creates a new window of class *pszClass* and returns *hwnd*.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwndParent;      /* Parent-window handle. */
PSZ     pszClass;        /* Registered-class name. */
PSZ     pszName;         /* Window text. */
ULONG   flStyle;         /* Window style. */
LONG    x;               /* x-coordinate of window position. */
LONG    y;               /* y-coordinate of window position. */
LONG    cx;              /* Width of window, in window coordinates. */
LONG    cy;              /* Height of window, in window coordinates. */
HWND    hwndOwner;       /* Owner-window handle. */
HWND    hwndInsertBehind; /* Sibling-window handle. */
ULONG   id;              /* Window identifier. */
PVOID   pCtlData;        /* Pointer to control data. */
PVOID   pPresParams;     /* Presentation parameters. */
HWND    hwnd;            /* Window handle. */

hwnd = WinCreateWindow(hwndParent, pszClass,
    pszName, flStyle, x, y, cx, cy, hwndOwner,
    hwndInsertBehind, id, pCtlData, pPresParams);
```

WinCreateWindow Parameter - hwndParent

hwndParent (HWND) - input
Parent-window handle.

If *hwndParent* is a desktop window handle, or is `HWND_DESKTOP`, a main window is created.

If *hwndParent* is `HWND_OBJECT`, or is a window handle returned by [WinQueryObjectWindow](#), an object window is created.

WinCreateWindow Parameter - pszClass

pszClass ([PSZ](#)) - input
Registered-class name.

pszClass is either an application-specified name as defined by [WinRegisterClass](#) or the name of a preregistered WC_* class.

This parameter can also be specified directly as a WC_* constant.

WinCreateWindow Parameter - pszName

pszName ([PSZ](#)) - input
Window text.

The actual structure of the data is class-specific. It is usually a null-terminated string that is often displayed in the window.

WinCreateWindow Parameter - flStyle

flStyle ([ULONG](#)) - input
Window style.

WinCreateWindow Parameter - x

x ([LONG](#)) - input
x-coordinate of window position.

The value is in window coordinates relative to the origin of the parent window.

WinCreateWindow Parameter - y

y ([LONG](#)) - input
y-coordinate of window position.

The value is in window coordinates relative to the origin of the parent window.

WinCreateWindow Parameter - cx

cx (**LONG**) - input
Width of window, in window coordinates.

WinCreateWindow Parameter - cy

cy (**LONG**) - input
Height of window, in window coordinates.

WinCreateWindow Parameter - hwndOwner

hwndOwner (**HWND**) - input
Owner-window handle.

Windows that send messages send them to their owner, as defined by this parameter. When an owner window is destroyed, all windows owned by it are also destroyed. The owner window must belong to the current thread.

WinCreateWindow Parameter - hwndInsertBehind

hwndInsertBehind (**HWND**) - input
Sibling-window handle.

This is the sibling window behind which *hwnd* is placed. If this parameter is **HWND_TOP** or **HWND_BOTTOM**, *hwnd* is placed on top of all, or behind all of its siblings. This parameter must be **HWND_TOP**, **HWND_BOTTOM**, or a child of *hwndParent*.

WinCreateWindow Parameter - id

id (**ULONG**) - input
Window identifier.

A value given by the application, that enables specific children of a window to be identified. For example, the controls of a dialog have unique identifiers so that an owner can distinguish which control has notified it. Window identifiers are also used for frame windows. It must be greater or equal to 0 and less or equal to 0xFFFF.

WinCreateWindow Parameter - pCtlData

pCtlData ([PVOID](#)) - input
Pointer to control data.

Pointer to a [Control-Data](#) data structure.

The data referenced by this pointer is class-specific data passed to the window procedure by the [WM_CREATE](#) message.

This parameter MUST be a pointer rather than a long.

The first 2 bytes in the data referenced by the pointer must be the total size of the data referenced by the pointer (for example see the [ENTRYFDATA](#) or the [FRAMECDATA](#) structures). PM requires this information to enable it to ensure that the referenced data is accessible to both 16-bit and 32-bit code.

WinCreateWindow Parameter - pPresParams

pPresParams ([PVOID](#)) - input
Presentation parameters.

This is class-specific presentation data passed to the window procedure by the [WM_CREATE](#) message.

WinCreateWindow Return Value - hwnd

hwnd ([HWND](#)) - returns
Window handle.

NULLHANDLE	Error occurred
Other	Window handle.

WinCreateWindow - Parameters

hwndParent ([HWND](#)) - input
Parent-window handle.

If *hwndParent* is a desktop window handle, or is [HWND_DESKTOP](#), a main window is created.

If *hwndParent* is [HWND_OBJECT](#), or is a window handle returned by [WinQueryObjectWindow](#), an object window is created.

pszClass ([PSZ](#)) - input
Registered-class name.

pszClass is either an application-specified name as defined by [WinRegisterClass](#) or the name of a preregistered [WC_*](#) class.

This parameter can also be specified directly as a [WC_*](#) constant.

pszName ([PSZ](#)) - input
Window text.

The actual structure of the data is class-specific. It is usually a null-terminated string that is often displayed in the window.

flStyle ([ULONG](#)) - input
Window style.

x ([LONG](#)) - input
x-coordinate of window position.

The value is in window coordinates relative to the origin of the parent window.

y ([LONG](#)) - input
y-coordinate of window position.

The value is in window coordinates relative to the origin of the parent window.

cx ([LONG](#)) - input
Width of window, in window coordinates.

cy ([LONG](#)) - input
Height of window, in window coordinates.

hwndOwner ([HWND](#)) - input
Owner-window handle.

Windows that send messages send them to their owner, as defined by this parameter. When an owner window is destroyed, all windows owned by it are also destroyed. The owner window must belong to the current thread.

hwndInsertBehind ([HWND](#)) - input
Sibling-window handle.

This is the sibling window behind which *hwnd* is placed. If this parameter is [HWND_TOP](#) or [HWND_BOTTOM](#), *hwnd* is placed on top of all, or behind all of its siblings. This parameter must be [HWND_TOP](#), [HWND_BOTTOM](#), or a child of *hwndParent*.

id ([ULONG](#)) - input
Window identifier.

A value given by the application, that enables specific children of a window to be identified. For example, the controls of a dialog have unique identifiers so that an owner can distinguish which control has notified it. Window identifiers are also used for frame windows. It must be greater or equal to 0 and less or equal to 0xFFFF.

pCtlData ([PVOID](#)) - input
Pointer to control data.

Pointer to a [Control-Data](#) data structure.

The data referenced by this pointer is class-specific data passed to the window procedure by the [WM_CREATE](#) message.

This parameter MUST be a pointer rather than a long.

The first 2 bytes in the data referenced by the pointer must be the total size of the data referenced by the pointer (for example see the [ENTRYFDATA](#) or the [FRAMECDATA](#) structures). PM requires this information to enable it to ensure that the referenced data is accessible to both 16-bit and 32-bit code.

pPresParams ([PVOID](#)) - input
Presentation parameters.

This is class-specific presentation data passed to the window procedure by the [WM_CREATE](#) message.

hwnd ([HWND](#)) - returns
Window handle.

NULLHANDLE
Error occurred
Other
Window handle.

WinCreateWindow - Remarks

The appearance and behavior of a window are determined by its style, which is the combination of the style established by *pszClass* and *//Style* ORed together. Any of the standard styles *WS_** can be used in addition to any class-specific styles that may be defined.

A window is usually created enabled and invisible. For more information on the initial state of a created window, see the list of the standard window styles.

Messages may be received from other processes or threads when this function is called.

This function sends the [WM_CREATE](#) message to the window procedure of the window being created.

This function sends the [WM_ADJUSTWINDOWPOS](#) message after the [WM_CREATE](#) message, and before the window is displayed (if applicable). The values passed are those given to the `WinCreateWindow` function. If the window has style *WS_VISIBLE*, the window is created visible.

The [WM_SIZE](#) message is not sent by the `WinCreateWindow` function while the window is being created. Any required size processing can be performed during the processing of the [WM_CREATE](#) message.

Because windows are often created with zero height or width and sized later, it is good practice not to perform any size-related processing if the size of the window is zero.

If the `WinCreateWindow` function is called for a window of class *WC_FRAME*, the controls specified by are created but not formatted. The frame is formatted when a [WM_FORMATFRAME](#) message is received but this is not sent during window creation. To cause the frame to format, either a [WM_FORMATFRAME](#) message must be sent, or the window position adjusted using the [WinSetWindowPos](#) function call which sends a [WM_SIZE](#) message if the position or size is changed.

The only limitation to the size and position specified for a window is the number range allowed for the size and position parameters; that is, an application can create windows that are larger than the screen or that are positioned partially or totally off the screen. However, the user interface for manipulation of window sizes and positions is affected if part or all of the window is off the screen.

It is recommended that part of the title bar be left on the screen, if the window has one, to enable the user to move the window around.

When a *WC_MENU* window is created with this call, *pCtiData* is assumed to be a menu template, which is used to create the menu. If *pCtiData* is *NULL*, an empty menu is created.

WinCreateWindow - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

PMERR_INVALID_FLAG (0x1019)
An invalid bit was set for a parameter. Use constants defined by PM for options, and do not set any reserved bits.

PMERR_NO_MSG_QUEUE (0x1036)

PMERR_INVALID_PARM (0x1303)
A parameter to the function contained invalid data.

PMERR_INVALID_PARAMETERS (0x1208)
An application parameter value is invalid for its converted PM type. For example: a 4-byte value outside the range -32 768 to +32 767 cannot be converted to a [SHORT](#), and a negative number cannot be converted to a [ULONG](#) or [USHORT](#).

WinCreateWindow - Example Code

This example creates a list box window named "List Box" as a child of the desktop located at (0,0), of size 200x100.

```
#define INCL_WINWINDOWMGR          /* Window Manager Functions */
#define INCL_WINLISTBOXES          /* List Box definitions      */
#include <os2.h>

HWND  hwnd;                        /* Cursor display window    */
ULONG ListBoxId;                  /* Window id                */
                                           /* (supplied by application) */
ULONG flStyle;                    /* Window style             */

flStyle = WS_VISIBLE;             /* Create window visible    */

/* Create button window */
hwnd = WinCreateWindow(HWND_DESKTOP, /* Parent window            */
                      WC_LISTBOX,    /* Class name               */
                      "List Box",    /* Window text              */
                      flStyle,        /* Window style             */
                      0, 0,           /* Position (x,y)           */
                      200, 100,       /* Size (width,height)      */
                      NULLHANDLE,     /* Owner window             */
                      HWND_TOP,       /* Sibling window           */
                      ListBoxId,      /* Window id                */
                      NULL,           /* Control data             */
                      NULL);          /* Pres parameters          */
```

WinDdeInitiate

WinDdeInitiate - Syntax

This function is issued by a client application to one or more other applications, to request initiation of a dynamic data exchange conversation with a national language conversation context.

```
#define INCL_WINDDE /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwndClient;    /* Client's window handle. */
PSZ       pszAppName;    /* Application name. */
PSZ       pszTopicName;  /* Topic name. */
PCONVCONTEXT pContext;   /* Conversation context. */
BOOL      rc;            /* Success indicator. */

rc = WinDdeInitiate(hwndClient, pszAppName,
                    pszTopicName, pContext);
```

WinDdeInitiate Parameter - hwndClient

hwndClient ([HWND](#)) - input
Client's window handle.

WinDdeInitiate Parameter - pszAppName

pszAppName ([PSZ](#)) - input
Application name.

This is the name of the desired server application. If it is a zero-length string, any application can respond.

Application names may not contain slashes or backslashes.

WinDdeInitiate Parameter - pszTopicName

pszTopicName ([PSZ](#)) - input
Topic name.

This is the name of the desired topic. If it is a zero-length string, each responding application will respond once for each topic which it can support.

WinDdeInitiate Parameter - pContext

pContext ([PCONVCONTEXT](#)) - input
Conversation context.

WinDdeInitiate Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

- | | |
|-------|---|
| TRUE | Successful completion. The WM_DDE_INITIATE message is successfully sent to all appropriate windows. |
| FALSE | Error occurred. |

WinDdeInitiate - Parameters

hwndClient ([HWND](#)) - input
Client's window handle.

pszAppName ([PSZ](#)) - input
Application name.

This is the name of the desired server application. If it is a zero-length string, any application can respond.

Application names may not contain slashes or backslashes.

pszTopicName ([PSZ](#)) - input
Topic name.

This is the name of the desired topic. If it is a zero-length string, each responding application will respond once for each topic which it can support.

pContext ([PCONVCONTEXT](#)) - input
Conversation context.

rc ([BOOL](#)) - returns
Success indicator.

- | | |
|-------|---|
| TRUE | Successful completion. The WM_DDE_INITIATE message is successfully sent to all appropriate windows. |
| FALSE | |

Error occurred.

WinDdeInitiate - Remarks

This function sends a [WM_DDE_INITIATE](#) message to all top level frame windows. These are windows registered with CS_FRAME, whose parent is the desktop window. No message is sent to object windows.

The WinDdeInitiate function does not return to the client application until all receiving applications have, in sequence, processed the [WM_DDE_INITIATE](#) message, and the client application has received all the corresponding [WM_DDE_INITIATEACK](#) messages (see [WinDdeRespond](#)).

To support DDE conversations between applications running in different memory models (16-bit and 32-bit) it is necessary to process all DDE messages in the application window procedure. The use of the [WinDispatchMsg](#) function ensures that conversion is performed on memory or segment addresses.

WinDdeInitiate - Example Code

This example uses WinDdeInitiate to initiate-during the creation of a client window-a dynamic data exchange (DDE) conversation with any available server applications, asking that the server applications respond for each topic they can support. It also allocates the shared memory that will be used once the conversation is established.

```
#define INCL_WINDDE          /* Window DDE Functions          */
#define INCL_DOSMEMMGR      /* Memory Manager values    */
#include <os2.h>

BOOL fSuccess;              /* success indicator        */
HWND hwndClient;           /* client window            */
char pszAppName[15]="";    /* server application       */
char pszTopicName[15]="";  /* topic                    */
CONVCONTEXT Context;
PDDESTRUCT pddeData;       /* DDE structure            */

case WM_CREATE:
    /* issue DDE initialize call */
    fSuccess = WinDdeInitiate(hwndClient, pszAppName,
```

```

        pszTopicName, &Context);

/* allocate shared memory for conversation data */
DosAllocSharedMem((PVOID)pddeData, "DDESHAREMEM",
    sizeof(DDESTRUCT) + 50,
    PAG_READ | PAG_WRITE | PAG_COMMIT |
    OBJ_GIVEABLE | OBJ_GETTABLE);

```

WinDdePostMsg

WinDdePostMsg - Syntax

This function is issued by an application to post a message to another application with which it is carrying out a dynamic data exchange conversation with a national language conversation context.

```

#define INCL_WINDDE /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwndTo;      /* Window handle of target. */
HWND      hwndFrom;    /* Window handle of originator. */
ULONG     usMsgId;     /* Message identifier. */
PDDESTRUCT pData;      /* Pointer to the DDE control structure being passed. */
ULONG     ulOptions;   /* Options. */
BOOL      rc;          /* Success indicator. */

rc = WinDdePostMsg(hwndTo, hwndFrom, usMsgId,
    pData, ulOptions);

```

WinDdePostMsg Parameter - hwndTo

hwndTo ([HWND](#)) - input
 Window handle of target.

WinDdePostMsg Parameter - hwndFrom

hwndFrom ([HWND](#)) - input
Window handle of originator.

WinDdePostMsg Parameter - usMsgId

usMsgId ([ULONG](#)) - input
Message identifier.

Identifies the message to be posted.

The following messages are valid:

[WM_DDE_ACK](#)
[WM_DDE_ADVISE](#)
[WM_DDE_DATA](#)
[WM_DDE_EXECUTE](#)
[WM_DDE_POKE](#)
[WM_DDE_REQUEST](#)
[WM_DDE_TERMINATE](#)
[WM_DDE_UNADVISE](#).

WinDdePostMsg Parameter - pData

pData ([PDDESTRUCT](#)) - input
Pointer to the DDE control structure being passed.

WinDdePostMsg Parameter - ulOptions

ulOptions ([ULONG](#)) - input
Options.

It must be one of the following values:

DDEPM_RETRY

This controls what happens if the message cannot be posted because the destination queue is full.

If this option is set, then message posting is retried at 1-second intervals, until the message is posted successfully. In this case, this function dispatches any messages in the queue of the application issuing this function, by calling the [WinPeekMsg](#) and [WinDispatchMsg](#) functions in a loop, so that messages sent by other applications can be received. This means that the application can continue to receive DDE messages (or other kinds of messages), while attempting to post DDE messages, thereby preventing deadlock between two applications whose queues are

full and who are both attempting to post a message to each other with this option set.

Applications which rely on inspecting messages prior to issuing the [WinPeekMsg](#) function can either, use the [WinSetHook](#) function and detect the above situation in the invoked hook procedure by testing the MSGF_DDEPOSTMSG value of the *msgf* parameter, or not use this option, in order to avoid the deadlock situation.

If this option is not set, then this function returns FALSE without retrying.

Note: If the message posting fails for any other reason (for example, an invalid window handle is specified), this function returns FALSE even if this option has been selected.

DDEPM_NOFREE

This option prevents the WinDdePostMsg call from freeing the shared memory block passed in on the pData parameter. If this option is used, the caller is responsible for freeing the memory block at some subsequent time (for example, the same memory block could be used in multiple calls to WinDdePostMsg and then freed once at the end of those calls.

If this option is not specified, the DDE structure will be freed.

WinDdePostMsg Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinDdePostMsg - Parameters

hwndTo ([HWND](#)) - input
Window handle of target.

hwndFrom ([HWND](#)) - input
Window handle of originator.

usMsgId ([ULONG](#)) - input
Message identifier.

Identifies the message to be posted.

The following messages are valid:

[WM_DDE_ACK](#)
[WM_DDE_ADVISE](#)
[WM_DDE_DATA](#)
[WM_DDE_EXECUTE](#)
[WM_DDE_POKE](#)
[WM_DDE_REQUEST](#)
[WM_DDE_TERMINATE](#)
[WM_DDE_UNADVISE](#).

pData ([PDDESTRUCT](#)) - input
Pointer to the DDE control structure being passed.

ulOptions ([ULONG](#)) - input

Options.

It must be one of the following values:

DDEPM_RETRY

This controls what happens if the message cannot be posted because the destination queue is full.

If this option is set, then message posting is retried at 1-second intervals, until the message is posted successfully. In this case, this function dispatches any messages in the queue of the application issuing this function, by calling the [WinPeekMsg](#) and [WinDispatchMsg](#) functions in a loop, so that messages sent by other applications can be received. This means that the application can continue to receive DDE messages (or other kinds of messages), while attempting to post DDE messages, thereby preventing deadlock between two applications whose queues are full and who are both attempting to post a message to each other with this option set.

Applications which rely on inspecting messages prior to issuing the [WinPeekMsg](#) function can either, use the [WinSetHook](#) function and detect the above situation in the invoked hook procedure by testing the MSGF_DDEPOSTMSG value of the *msgf* parameter, or not use this option, in order to avoid the deadlock situation.

If this option is not set, then this function returns FALSE without retrying.

Note: If the message posting fails for any other reason (for example, an invalid window handle is specified), this function returns FALSE even if this option has been selected.

DDEPM_NOFREE

This option prevents the WinDdePostMsg call from freeing the shared memory block passed in on the pData parameter. If this option is used, the caller is responsible for freeing the memory block at some subsequent time (for example, the same memory block could be used in multiple calls to WinDdePostMsg and then freed once at the end of those calls.

If this option is not specified, the DDE structure will be freed.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinDdePostMsg - Remarks

To support DDE conversations between applications running in different memory models (16-bit and 32-bit) it is necessary to process all DDE messages in the application window procedure. The use of the [WinDispatchMsg](#) function ensures that conversion is performed on memory or segment addresses.

WinDdeRespond

WinDdeRespond - Syntax

This function is issued by a server application to indicate that it can support a dynamic data exchange conversation on a particular topic with a national language conversation context.

```
#define INCL_WINDDE /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwndClient; /* Client's window handle. */
HWND      hwndServer; /* Server's window handle. */
PSZ       pszAppName; /* Application name. */
PSZ       pszTopicName; /* Topic name. */
PCONVCONTEXT pContext; /* Conversation context. */
MRESULT    mresReply; /* Message return data. */

mresReply = WinDdeRespond(hwndClient, hwndServer,
                          pszAppName, pszTopicName, pContext);
```

WinDdeRespond Parameter - hwndClient

hwndClient ([HWND](#)) - input
Client's window handle.

WinDdeRespond Parameter - hwndServer

hwndServer ([HWND](#)) - input
Server's window handle.

If a server application is responding for more than one topic, it must use a different window for each topic.

WinDdeRespond Parameter - pszAppName

pszAppName ([PSZ](#)) - input
Application name.

This is the name of the responding server application. It must not be a zero-length string or null.

Application names may not contain slashes or backslashes.

WinDdeRespond Parameter - pszTopicName

pszTopicName ([PSZ](#)) - input
Topic name.

This is the name of the topic which the server is willing to support. It must not be a zero-length string or null.

WinDdeRespond Parameter - pContext

pContext ([PCONVCONTEXT](#)) - input
Conversation context.

WinDdeRespond Return Value - mresReply

mresReply ([MRESULT](#)) - returns
Message return data.

WinDdeRespond - Parameters

hwndClient ([HWND](#)) - input
Client's window handle.

hwndServer ([HWND](#)) - input
Server's window handle.

If a server application is responding for more than one topic, it must use a different window for each topic.

pszAppName ([PSZ](#)) - input
Application name.

This is the name of the responding server application. It must not be a zero-length string or null.

Application names may not contain slashes or backslashes.

pszTopicName ([PSZ](#)) - input
Topic name.

This is the name of the topic which the server is willing to support. It must not be a zero-length string or null.

pContext ([PCONVCONTEXT](#)) - input
Conversation context.

mresReply ([MRESULT](#)) - returns
Message return data.

WinDdeRespond - Remarks

This function is issued by a server application after receiving a [WM_DDE_INITIATE](#) message that identifies this server application (or indicates that any application can respond), and also either identifies a particular topic which the server can support, or asks for all supported topics (see [WinDdeInitiate](#)). This function sends a [WM_DDE_INITIATEACK](#) message back to the client, that is the sender of the [WM_DDE_INITIATE](#) message.

If the server application can respond, it issues this function once if a specific topic was requested, or once for each topic which it can support, if all supported topics were requested.

A DDE conversation is initiated each time this function is successfully issued. The client is expected to terminate all unwanted conversations. Once a conversation is initiated, it is controlled by the client issuing [WinDdePostMsg](#) functions.

To support DDE conversations between applications running in different memory models (16-bit and 32-bit) it is necessary to process all DDE messages in the application window procedure. The use of the [WinDispatchMsg](#) function ensures that conversion is performed on memory or segment addresses.

WinDdeRespond - Example Code

This example uses WinDdeRespond to respond to an initiate message (WM_DDEINITIATE) generated by the client window issuing WinDdeInitiate. Here, the server responds as a DDE Server that supports a System topic.

```
#define INCL_WINDDE          /* Window DDE Functions          */
#include <os2.h>

HWND  hwndClient;          /* client window          */
HWND  hwndServer;          /* server window           */
char  pszAppName[15]="DDE Server"; /* server application      */
char  pszTopicName[15]=SZDDESYS_TOPIC; /* topic ('System')       */
MRESULT mresReply;          /* message return data     */
CONVCONTEXT Context;

case WM_DDE_INITIATE:
    mresReply = WinDdeRespond(hwndClient, hwndServer, pszAppName,
                              pszTopicName, &Context);
```

WinDefDlgProc

WinDefDlgProc - Syntax

This function invokes the default dialog procedure with *hwndDlg*, *msg*, *mp1*, and *mp2*.

```
#define INCL_WINDIALOGS /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HWND      hwndDlg;          /* Dialog-window handle. */
ULONG     msg;              /* Message identity. */
MPARAM    mp1;              /* Parameter 1. */
MPARAM    mp2;              /* Parameter 2. */
```

```
MRESULT mresReply; /* Message-return data. */  
  
mresReply = WinDefDlgProc(hwndDlg, msg, mp1,  
mp2);
```

WinDefDlgProc Parameter - hwndDlg

hwndDlg ([HWND](#)) - input
Dialog-window handle.

WinDefDlgProc Parameter - msg

msg ([ULONG](#)) - input
Message identity.

WinDefDlgProc Parameter - mp1

mp1 ([MPARAM](#)) - input
Parameter 1.

WinDefDlgProc Parameter - mp2

mp2 ([MPARAM](#)) - input
Parameter 2.

WinDefDlgProc Return Value - mresReply

mresReply ([MRESULT](#)) - returns
Message-return data.

WinDefDlgProc - Parameters

hwndDlg ([HWND](#)) - input
Dialog-window handle.

msg ([ULONG](#)) - input
Message identity.

mp1 ([MPARAM](#)) - input
Parameter 1.

mp2 ([MPARAM](#)) - input
Parameter 2.

mresReply ([MRESULT](#)) - returns
Message-return data.

WinDefDlgProc - Remarks

The action taken by the default dialog procedure is such that the values passed in *mp1* and *mp2*, and the values returned in *mresReply* are defined for each *msg*.

The default dialog procedure provides default processing for any dialog window messages that an application chooses not to process. It can be used to ensure that every message is processed and is called with the same parameters that were received by the dialog procedure.

The action of the WinDefDlgProc function on receiving messages is precisely the same as for the frame window procedure except for WM_CLOSE messages where WinDismissDlg will be called. If an application processes a message instead of sending it to the WinDefDlgProc function, it may be required to perform some or all of the frame window procedure actions for itself.

WinDefDlgProc - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinDefDlgProc - Example Code

This example shows a typical dialog box procedure. A switch statement is used to process individual messages. All messages not processed are passed on to the WinDefDlgProc function.

```
#define INCL_WINDIALOGS          /* Window Dialog Mgr Functions */
#include <os2.h>

MRESULT AboutDlg(HWND hwnd, ULONG ulMessage, MPARAM mpParam1,
                  MPARAM mpParam2)
{
    switch (ulMessage) {

        /*
         * Process whatever messages you want here and send the rest
         * to WinDefDlgProc.
         */

        default:
            return (WinDefDlgProc(hwnd, ulMessage, mpParam1, mpParam2));
    }
}
```

WinDefFileDlgProc

WinDefFileDlgProc - Syntax

This function is the default dialog procedure for the file dialog.

```
#define INCL_winstdfile
#include <os2.h>

HWND      hwnd;          /* Dialog-window handle. */
ULONG     msg;           /* Message identity. */
MPARAM    mp1;           /* Parameter 1. */
MPARAM    mp2;           /* Parameter 2. */
MRESULT   mresReply;     /* Message-return data. */

mresReply = WinDefFileDlgProc(hwnd, msg, mp1,
                               mp2);
```

WinDefFileDlgProc Parameter - hwnd

hwnd ([HWND](#)) - input
Dialog-window handle.

WinDefFileDlgProc Parameter - msg

msg ([ULONG](#)) - input
Message identity.

WinDefFileDlgProc Parameter - mp1

mp1 ([MPARAM](#)) - input
Parameter 1.

WinDefFileDlgProc Parameter - mp2

mp2 ([MPARAM](#)) - input
Parameter 2.

WinDefFileDlgProc Return Value - mresReply

mresReply ([HRESULT](#)) - returns
Message-return data.

WinDefFileDlgProc - Parameters

hwnd ([HWND](#)) - input

Dialog-window handle.

msg ([ULONG](#)) - input
Message identity.

mp1 ([MPARAM](#)) - input
Parameter 1.

mp2 ([MPARAM](#)) - input
Parameter 2.

mresReply ([MRESULT](#)) - returns
Message-return data.

WinDefFileDlgProc - Remarks

All unprocessed messages in a custom dialog procedure should be passed to the default file dialog procedure so that the dialog can implement its default behavior.

WinDefFileDlgProc - Example Code

This example uses the default dialog procedure for the file dialog to cause default processing of unprocessed dialog messages.

```
#define INCL_WINSTDFILE  /* Window Standard File Functions      */
#include <os2.h>

MRESULT MyFileDlgProc(HWND hwnd, ULONG msg, MPARAM mpParam1,
                      MPARAM mpParam2)
{
    switch(msg)
    {
        /******
        /* Process user-supported messages
        /******
        .
        .
        .
        default:
            return (WinDefFileDlgProc(hwnd, msg, mpParam1, mpParam2));
    }
}
```

WinDefFontDlgProc

WinDefFontDlgProc - Syntax

This function is the default dialog procedure for the font dialog.

```
#define INCL_winstdfont
#include <os2.h>

HWND      hwnd;      /* Dialog-window handle. */
ULONG     msg;        /* Message identity. */
MPARAM    mp1;        /* Parameter 1. */
MPARAM    mp2;        /* Parameter 2. */
MRESULT    mresReply; /* Message-return data. */

mresReply = WinDefFontDlgProc(hwnd, msg, mp1,
                               mp2);
```

WinDefFontDlgProc Parameter - hwnd

hwnd (**HWND**) - input
Dialog-window handle.

WinDefFontDlgProc Parameter - msg

msg (**ULONG**) - input
Message identity.

WinDefFontDlgProc Parameter - mp1

mp1 (**MPARAM**) - input
Parameter 1.

WinDefFontDlgProc Parameter - mp2

mp2 (**MPARAM**) - input
Parameter 2.

WinDefFontDlgProc Return Value - mresReply

mresReply (**MRESULT**) - returns
Message-return data.

WinDefFontDlgProc - Parameters

hwnd (**HWND**) - input
Dialog-window handle.

msg (**ULONG**) - input
Message identity.

mp1 (**MPARAM**) - input
Parameter 1.

mp2 (**MPARAM**) - input
Parameter 2.

mresReply (**MRESULT**) - returns
Message-return data.

WinDefFontDlgProc - Remarks

All unprocessed messages in a custom dialog procedure should be passed to the default font dialog procedure so that the dialog can implement its default behavior.

WinDefFontDlgProc - Example Code

This example uses the default dialog procedure for the font dialog to cause default processing of unprocessed dialog messages.

```
#define INCL_WINSTDFONT /* Window Standard Font Functions */
#include <os2.h>

MRESULT MyFontDlgProc(HWND hwnd, ULONG msg, MPARAM mpParam1,
                      MPARAM mpParam2)
{
    switch(msg)
    {
        /*****
        *****/
```

```

/* Process user-supported messages */
/*****
.
.
.
default:
    return (WinDefFontDlgProc(hwnd, msg, mpParam1, mpParam2));
}
}

```

WinDefWindowProc

WinDefWindowProc - Syntax

This function invokes the default window procedure.

```

#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HWND      hwnd;      /* Window handle. */
ULONG     ulMsgid;    /* Message identity. */
MPARAM    mpParam1;   /* Parameter 1. */
MPARAM    mpParam2;   /* Parameter 2. */
MRESULT   mresReply;  /* Message-return data. */

mresReply = WinDefWindowProc(hwnd, ulMsgid,
                             mpParam1, mpParam2);

```

WinDefWindowProc Parameter - hwnd

hwnd (**HWND**) - input
Window handle.

WinDefWindowProc Parameter - ulMsgid

ulMsgid ([ULONG](#)) - input
Message identity.

WinDefWindowProc Parameter - mpParam1

mpParam1 ([MPARAM](#)) - input
Parameter 1.

WinDefWindowProc Parameter - mpParam2

mpParam2 ([MPARAM](#)) - input
Parameter 2.

WinDefWindowProc Return Value - mresReply

mresReply ([MRESULT](#)) - returns
Message-return data.

WinDefWindowProc - Parameters

hwnd ([HWND](#)) - input
Window handle.

ulMsgid ([ULONG](#)) - input
Message identity.

mpParam1 ([MPARAM](#)) - input
Parameter 1.

mpParam2 ([MPARAM](#)) - input
Parameter 2.

mresReply ([MRESULT](#)) - returns
Message-return data.

WinDefWindowProc - Remarks

The default window provides default processing for any window messages that an application chooses not to process. It can be used to ensure that every message is processed. This function should be made with the same parameters as those received by the window procedure.

The action taken by the default window procedure, the values passed in *mpParam1*, *mpParam2* and the values returned in *mresReply* are defined for each *ulMsgid*.

WinDefWindowProc - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinDeleteAtom

WinDeleteAtom - Syntax

This function deletes an atom from an atom table.

```
#define INCL_WINATOM /* Or use INCL_WIN, INCL_PM, */  
#include <os2.h>  
  
HATOMTBL    hatomtblAtomTbl; /* Atom-table handle. */  
ATOM         atom;           /* Atom identifying the atom to be deleted. */  
ATOM         rc;             /* Return code. */  
  
rc = WinDeleteAtom(hatomtblAtomTbl, atom);
```

WinDeleteAtom Parameter - hatomtblAtomTbl

hatomtblAtomTbl ([HATOMTBL](#)) - input
Atom-table handle.

This is the handle returned from a previous [WinCreateAtomTable](#) or [WinQuerySystemAtomTable](#) function.

WinDeleteAtom Parameter - atom

atom ([ATOM](#)) - input
Atom identifying the atom to be deleted.

WinDeleteAtom Return Value - rc

rc ([ATOM](#)) - returns
Return code.

0	Call successful
Other	The call fails and the atom has not been deleted, in which case this is equal to the <i>atom</i> parameter.

WinDeleteAtom - Parameters

hatomtblAtomTbl ([HATOMTBL](#)) - input
Atom-table handle.

This is the handle returned from a previous [WinCreateAtomTable](#) or [WinQuerySystemAtomTable](#) function.

atom ([ATOM](#)) - input
Atom identifying the atom to be deleted.

rc ([ATOM](#)) - returns
Return code.

0	Call successful
Other	The call fails and the atom has not been deleted, in which case this is equal to the <i>atom</i> parameter.

WinDeleteAtom - Remarks

If the passed atom is an integer atom, 0 is returned. If it is not an integer atom and it is a valid atom for the given atom table, that is, it has an atom name and use count, its use count is decremented by one and 0 is returned. If the use count has been decremented to zero, the atom name and use count are removed from the atom table.

WinDeleteAtom - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HATOMTBL (0x1013)
An invalid atom-table handle was specified.

PMERR_INVALID_ATOM (0x1014)

The specified atom does not exist in the atom table.

WinDeleteLboxItem

WinDeleteLboxItem - Syntax

This macro deletes the indexed item from the List Box. It returns the number of items left.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwndLbox; /* Listbox handle. */
LONG    index;    /* Index of the listbox item. */
LONG    lItems;   /* Number of items left. */

lItems = WinDeleteLboxItem(hwndLbox, index);
```

WinDeleteLboxItem Parameter - hwndLbox

hwndLbox (HWND) - input
Listbox handle.

WinDeleteLboxItem Parameter - index

index (LONG) - input
Index of the listbox item.

WinDeleteLboxItem Return Value - lItems

lItems (LONG) - returns
Number of items left.

WinDeleteLboxItem - Parameters

hwndLbox ([HWND](#)) - input
Listbox handle.

index ([LONG](#)) - input
Index of the listbox item.

lItems ([LONG](#)) - returns
Number of items left.

WinDeleteLboxItem - Remarks

This macro is defined as:

```
#define WinDeleteLboxItem(hwndLbox, index) \
    ((LONG)WinSendMessage(hwndLbox, \
        LM_DELETEITEM, \
        MPFROMLONG(index), \
        (MPARAM)NULL))
```

This macro requires the existence of a message queue.

WinDeleteLibrary

WinDeleteLibrary - Syntax

This function deletes the library *hlibLibhandle*, which is previously loaded by the [WinLoadLibrary](#) function.

```

#define INCL_WINLOAD /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
HLIB     hlibLibhandle; /* Library handle to be deleted. */
BOOL     rc;           /* Library-deleted indicator. */

rc = WinDeleteLibrary(hab, hlibLibhandle);

```

WinDeleteLibrary Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinDeleteLibrary Parameter - hlibLibhandle

hlibLibhandle ([HLIB](#)) - input
Library handle to be deleted.

This handle was previously loaded by the the [WinLoadLibrary](#) function.

WinDeleteLibrary Return Value - rc

rc ([BOOL](#)) - returns
Library-deleted indicator.

TRUE	Library successfully deleted
FALSE	Library not successfully deleted.

WinDeleteLibrary - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

hlibLibhandle ([HLIB](#)) - input
Library handle to be deleted.

WinDeregisterObjectClass

WinDeregisterObjectClass - Syntax

This function deregisters (removes) a workplace object class.

```
#define INCL_WINWORKPLACE
#include <os2.h>

PSZ     pszClassName;      /* Pointer to class name. */
BOOL    rc;                /* Success indicator. */

rc = WinDeregisterObjectClass(pszClassName);
```

WinDeregisterObjectClass Parameter - pszClassName

pszClassName ([PSZ](#)) - input
Pointer to class name.

A pointer to a zero-terminated string which contains the name of the object class being removed from the workplace.

WinDeregisterObjectClass Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinDeregisterObjectClass - Parameters

pszClassName ([PSZ](#)) - input
Pointer to class name.

A pointer to a zero-terminated string which contains the name of the object class being removed from the workplace.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinDeregisterObjectClass - Remarks

Workplace object classes are not deleted unless the application issues a WinDeregisterObjectClass. Object classes will be automatically registered when a dynamic-link library containing an object definition is added to the system. The only advantage of deregistering an object class is to optimize the system performance. All registered classes are maintained in the OS2.INI and are cached upon system initialization. If the class is no longer needed, it should be removed.

WinDeregisterObjectClass - Related Functions

WinDestroyAccelTable

WinDestroyAccelTable - Syntax

This function destroys an accelerator table.

```
#define INCL_WINACCELERATORS /* Or use INCL_WIN, INCL_PM, */  
#include <os2.h>  
  
HACCEL    haccelAccel; /* Accelerator-table handle. */  
BOOL      rc;          /* Success indicator. */  
  
rc = WinDestroyAccelTable(haccelAccel);
```

WinDestroyAccelTable Parameter - haccelAccel

haccelAccel ([HACCEL](#)) - input
Accelerator-table handle.

WinDestroyAccelTable Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinDestroyAccelTable - Parameters

haccelAccel ([HACCEL](#)) - input
Accelerator-table handle.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinDestroyAccelTable - Remarks

Before an application is terminated, it should call the WinDestroyAccelTable function for every accelerator table that is created with the [WinCreateAccelTable](#) function.

WinDestroyAccelTable - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HACCEL (0x101A)
An invalid accelerator-table handle was specified.

WinDestroyAtomTable

WinDestroyAtomTable - Syntax

This function destroys a private atom table, which is created by [WinCreateAtomTable](#).

```

#define INCL_WINATOM /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HATOMTBL    hatomtblAtomTbl; /* Atom-table handle. */
HATOMTBL    rc;              /* Return code. */

rc = WinDestroyAtomTable(hatomtblAtomTbl);

```

WinDestroyAtomTable Parameter - hatomtblAtomTbl

hatomtblAtomTbl ([HATOMTBL](#)) - input
Atom-table handle.

This is the handle returned from a previous call to the [WinCreateAtomTable](#) function. If NULL then this function does nothing.

WinDestroyAtomTable Return Value - rc

rc (HATOMTBL) - returns	Return code.
0	Function successful.
Other	The call fails and the atom table has not been destroyed, in which case this is equal to the <i>hatomtblAtomTbl</i> parameter.

WinDestroyAtomTable - Parameters

hatomtblAtomTbl (HATOMTBL) - input	Atom-table handle.
This is the handle returned from a previous call to the WinCreateAtomTable function. If NULL then this function does nothing.	
rc (HATOMTBL) - returns	Return code.
0	Function successful.
Other	The call fails and the atom table has not been destroyed, in which case this is equal to the <i>hatomtblAtomTbl</i> parameter.

WinDestroyAtomTable - Remarks

This function makes no attempt to ensure that the handle to the atom table is not reused by a later call to the [WinCreateAtomTable](#) function.

The system atom table (see the [WinQuerySystemAtomTable](#) function) cannot be destroyed.

WinDestroyAtomTable - Errors

Possible returns from WinGetLastError
PMERR_INVALID_HATOMTBL (0x1013)
An invalid atom-table handle was specified.

WinDestroyAtomTable - Example Code

This example destroys an Atom Table of one atom, based on its handle, which is returned by WinCreateAtomTable.

```
#define INCL_WINATOM                /* Window Atom Functions          */
#include <os2.h>

ATOM atom;                          /* new atom value                */
HATOMTBL hatomtblAtomTbl; /* atom-table handle            */
HATOMTBL hatomtblDestroy; /* result of destroy table      */
char pszAtomName[10]; /* atom name                    */
USHORT usInitial = 0; /* initial atom table size (use default)*/
USHORT usBuckets = 0; /* size of hash table (use default) */

/* create atom table of default size */
hatomtblAtomTbl = WinCreateAtomTable(usInitial, usBuckets);

/* define name for new atom and add to table */
strcpy(pszAtomName, "newatom");
atom = WinAddAtom(hatomtblAtomTbl, pszAtomName);

hatomtblDestroy = WinDestroyAtomTable(hatomtblAtomTbl);
```

WinDestroyCursor

WinDestroyCursor - Syntax

This function destroys the current cursor, if it belongs to the specified window.

```
#define INCL_WINCursors /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HWND    hwnd; /* Window handle to which the cursor belongs. */
BOOL    rc;    /* Success indicator. */

rc = WinDestroyCursor(hwnd);
```

WinDestroyCursor Parameter - hwnd

hwnd (**HWND**) - input
Window handle to which the cursor belongs.

WinDestroyCursor Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinDestroyCursor - Parameters

hwnd (**HWND**) - input
Window handle to which the cursor belongs.

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinDestroyCursor - Remarks

This function has no effect if the current cursor does not belong to the specified window.

It is not necessary to call this function before calling the [WinCreateCursor](#) function.

If the cursor was created with the CURSOR_FLASH option, then the TID_CURSOR timer is also destroyed.

WinDestroyCursor - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinDestroyHelpInstance

WinDestroyHelpInstance - Syntax

This function destroys the specified instance of the Help Manager.

```
#define INCL_WINHELP /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwndHelpInstance; /* Handle of the instance of the Help Manager to be destroyed. */
BOOL    rc;                /* Success indicator. */

rc = WinDestroyHelpInstance(hwndHelpInstance);
```

WinDestroyHelpInstance Parameter - hwndHelpInstance

hwndHelpInstance ([HWND](#)) - input
Handle of the instance of the Help Manager to be destroyed.

This is the handle returned by the [WinCreateHelpInstance](#) call.

WinDestroyHelpInstance Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinDestroyHelpInstance - Parameters

hwndHelpInstance ([HWND](#)) - input
Handle of the instance of the Help Manager to be destroyed.

This is the handle returned by the [WinCreateHelpInstance](#) call.

rc ([BOOL](#)) - returns

Success indicator.

TRUE

Successful completion

FALSE

Error occurred.

WinDestroyHelpInstance - Example Code

This example shows a typical main function for an application which uses help. Following creation of the main application window the Help Manager is initialized and associated with the window. The help table is defined in the application's resources. When the window is destroyed, terminating the application, the help instance is also destroyed.

```
#define INCL_WIN
#include <os2.h>

#define IDHT_APPLICATION      100      /* id of HELP TABLE in resource file
*/

main( int argc, char *argv[], char *envp[] )
{
    HAB hab = WinInitialize( 0 );
    HMQ hmq = WinCreateMsgQueue( hab, 0 );
    HWND hwnd;
    HWND hwndClient;
    HWND hwndHelp;
    QMSG qmsg;
    ULONG flStyle;
    HELPINIT helpinit;

    /* Setup the help initialization structure */
    helpinit.cb = sizeof( HELPINIT );
    helpinit.ulReturnCode = 0L;
    helpinit.pszTutorialName = (PSZ)NULL;
    /* Help table in application resource */
    helpinit.phtHelpTable = (PHELPTABLE)MAKEULONG( IDHT_APPLICATION, 0xffff );
    helpinit.hmodHelpTableModule = NULLHANDLE;
    /* Default action bar and accelerators */
    helpinit.hmodAccelActionBarModule = NULLHANDLE;
    helpinit.idAccelTable = 0;
    helpinit.idActionBar = 0;
    helpinit.pszHelpWindowTitle = "APPNAME HELP";
    helpinit.fShowPanelId = CMIC_SHOW_PANEL_ID;
    helpinit.pszHelpLibraryName = "APPNAME.HLP";

    /* Register the class */
    if( WinRegisterClass( ... ) )
    {
        /* create the main window */
        flStyle = FCF_STANDARD;
        hwnd = WinCreateStdWindow( ... );
```

```

if( hwnd )
{
    /* Create and associate the help instance */
    hwndHelp = WinCreateHelpInstance( hab, &helpinit );

    if( hwndHelp && WinAssociateHelpInstance( hwndHelp, hwnd ) )
    {
        /* Process messages */
        while( WinGetMsg( hab, &qmsg, NULLHANDLE, 0, 0 ) )
        {
            WinDispatchMsg( hab, &qmsg );
        } /* endwhile */
    }

    /* Remove help instance - note: add */
    /*      WinAssociateHelpInstance( NULLHANDLE, hwnd ); */
    /* to WM_DESTROY processing to remove the association. */
    WinDestroyHelpInstance( hwndHelp );
}

/* finish the cleanup and exit */
WinDestroyMsgQueue( hmq );
WinTerminate( hab );
}

WinDestroyMsgQueue

WinDestroyMsgQueue - Syntax

This function destroys the message queue.

```

#define INCL_WINMESSAGEGR /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HMQ    hmq; /* Message-queue handle. */
BOOL    rc; /* Queue-destroyed indicator. */

rc = WinDestroyMsgQueue(hmq);

```

WinDestroyMsgQueue Parameter - hmq

hmq ([HMQ](#)) - input
Message-queue handle.

WinDestroyMsgQueue Return Value - rc

rc ([BOOL](#)) - returns
Queue-destroyed indicator.

TRUE	Queue destroyed
FALSE	Queue not destroyed.

WinDestroyMsgQueue - Parameters

hmq ([HMQ](#)) - input
Message-queue handle.

rc ([BOOL](#)) - returns
Queue-destroyed indicator.

TRUE	Queue destroyed
FALSE	Queue not destroyed.

WinDestroyMsgQueue - Remarks

This function must be called before terminating a thread or an application. Only the thread that called [WinCreateMsgQueue](#) may call this function with that handle.

WinDestroyMsgQueue - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HMQ (0x1002)
An invalid message-queue handle was specified.

WinDestroyObject

WinDestroyObject - Syntax

This function is called to delete a workplace object.

```
#define INCL_WINWORKPLACE
#include <os2.h>

HOBJECT    object; /* Handle to a workplace object. */
BOOL       rc;      /* Success indicator. */

rc = WinDestroyObject(object);
```

WinDestroyObject Parameter - object

object ([HOBJECT](#)) - input
Handle to a workplace object.

WinDestroyObject Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion.
FALSE	Error occurred.

WinDestroyObject - Parameters

object ([HOBJECT](#)) - input
Handle to a workplace object.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion.
FALSE	Error occurred.

WinDestroyObject - Remarks

The WinDestroyObject function will permanently remove an object that was created with the WinCreateObject function.
Using [HOBJECT](#) for .INI files or files in which an application uses a rename/save/delete sequence is not supported.

WinDestroyPointer

WinDestroyPointer - Syntax

This function destroys a pointer or icon.

```
#define INCL_WINPOINTERS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HPOINTER    hptrPointer; /* Handle of pointer to be destroyed. */
BOOL        rc;          /* Success indicator. */

rc = WinDestroyPointer(hptrPointer);
```

WinDestroyPointer Parameter - hptrPointer

hptrPointer (**HPOINTER**) - input
Handle of pointer to be destroyed.

WinDestroyPointer Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinDestroyPointer - Parameters

hptrPointer (**HPOINTER**) - input
Handle of pointer to be destroyed.

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinDestroyPointer - Remarks

A pointer can only be destroyed by the thread that created it.

The system pointers and icons must not be destroyed.

WinDestroyPointer - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HPTR (0x101B)
An invalid pointer handle was specified.

WinDestroyWindow

WinDestroyWindow - Syntax

This call destroys a window and its child windows.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HWND    hwnd; /* Window handle. */
BOOL    rc;    /* Window-destroyed indicator. */

rc = WinDestroyWindow(hwnd);
```

WinDestroyWindow Parameter - hwnd

hwnd ([HWND](#)) - input
Window handle.

WinDestroyWindow Return Value - rc

rc ([BOOL](#)) - returns
Window-destroyed indicator.

TRUE	Window destroyed
FALSE	Window not destroyed.

WinDestroyWindow - Parameters

hwnd ([HWND](#)) - input
Window handle.

rc ([BOOL](#)) - returns
Window-destroyed indicator.

TRUE	Window destroyed
FALSE	Window not destroyed.

WinDestroyWindow - Remarks

The window to be destroyed must have been created by the thread that is issuing this call. Before *hwnd* is itself destroyed, all child windows of *hwnd* are also destroyed.

If *hwnd* cannot be destroyed, for example because *hwnd* is an invalid window handle or is not associated with the current thread, *rc* returns FALSE.

Note: If *hwnd* is locked, this call does not return until the window is unlocked (and destroyed).

Messages may be received from other processes or threads during the processing of this call.

If a Presentation Space is associated with the window, it is disassociated from it by this function. If the presentation space was obtained by use of [GpiCreatePS](#) then it is disassociated from the window, but not destroyed. That is, this function calls [GpiAssociate](#) to disassociate the presentation space but does not call [GpiDestroyPS](#). If the presentation space was obtained by use of the [WinGetPS](#) function, it is released by this function; that is, this function performs the [WinReleasePS](#) function.

Messages sent by this call are:

[WM_DESTROY](#)

Always sent to the window being destroyed after the window has been hidden on the device, but before its child windows have been destroyed. The message is sent first to the window being destroyed, then to the child windows as they are destroyed. Therefore, during processing the [WM_DESTROY](#) it can be assumed that all the children still exist.

[WM_ACTIVATE](#)

Sent with if the window being destroyed is the active window.

[WM_RENDERALLFORMATS](#)

Sent if the clipboard owner is being destroyed, and there are unrendered formats in the clipboard.

If the window being destroyed is the active window, both the active window and the input focus window are transferred to another window when the window is destroyed. The window that becomes the active window is the next window, as defined for the "Alt+Esc" function. This usually corresponds to the next application in the sequence. The input focus transfers to whichever window the new active window decides should have it.

If a menu window is being destroyed, any bit maps associated with the menu are not deleted. They will be deleted automatically when the application terminates.

WinDestroyWindow - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinDismissDlg

WinDismissDlg - Syntax

This function hides the modeless dialog window, and causes [WinProcessDlg](#) or [WinDlgBox](#) to return.

```
#define INCL_WINDIALOGS /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HWND     hwndDlg; /* Dialog-window handle. */
ULONG    usResult; /* Reply value. */
BOOL     rc;       /* Dialog-dismissed indicator. */

rc = WinDismissDlg(hwndDlg, usResult);
```

WinDismissDlg Parameter - hwndDlg

hwndDlg ([HWND](#)) - input
Dialog-window handle.

WinDismissDlg Parameter - usResult

usResult ([ULONG](#)) - input
Reply value.

Returned to the caller of [WinProcessDlg](#) or [WinDlgBox](#).

WinDismissDlg Return Value - rc

rc ([BOOL](#)) - returns
Dialog-dismissed indicator.

TRUE	Dialog successfully dismissed
FALSE	Dialog not successfully dismissed.

WinDismissDlg - Parameters

hwndDlg ([HWND](#)) - input
Dialog-window handle.

usResult ([ULONG](#)) - input
Reply value.

Returned to the caller of [WinProcessDlg](#) or [WinDlgBox](#).

rc ([BOOL](#)) - returns
Dialog-dismissed indicator.

TRUE	Dialog successfully dismissed
FALSE	Dialog not successfully dismissed.

WinDismissDlg - Remarks

This function is required to complete the processing of a modal dialog window and is called from its dialog procedure. It is made implicitly if the dialog procedure passes a [WM_COMMAND](#) message to [WinDefDlgProc](#) or if a [WM_QUIT](#) message is encountered during [WinProcessDlg](#) or [WinGetDlgMsg](#).

This function hides the dialog window, and re-enables any windows that were disabled by [WinProcessDlg](#) or [WinGetDlgMsg](#).

If the dialog window needs to be processed through [WinProcessDlg](#), after being dismissed, the [FF_DLGDISMISSED](#) flag must be reset.

It does not destroy the dialog window; [WinDestroyWindow](#) must be issued to destroy the dialog window when it is no longer needed. However, [WinDlgBox](#) destroys the dialog window it creates, when the dialog window is dismissed by the use of this function.

This function can be issued during the processing of the the [WM_INITDLG \(Default Dialogs\)](#) message.

Note: This function can be made from a modeless dialog window, although this is not necessary as there is no internal message processing loop. If it is called, the dialog window is hidden and it is the responsibility of the application to destroy the dialog window, if required.

WinDismissDlg - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)

An invalid window handle was specified.

WinDispatchMsg

WinDispatchMsg - Syntax

This function invokes a window procedure.

```
#define INCL_WINMESSAGEGR /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
PQMSG    pqmsgMsg;     /* Message structure. */
MRESULT  mresReply;    /* Message-return data. */

mresReply = WinDispatchMsg(hab, pqmsgMsg);
```

WinDispatchMsg Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinDispatchMsg Parameter - pqmsgMsg

pqmsgMsg ([PQMSG](#)) - input
Message structure.

WinDispatchMsg Return Value - mresReply

mresReply ([MRESULT](#)) - returns
Message-return data.

WinDispatchMsg - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

pqmsgMsg ([PQMSG](#)) - input
Message structure.

mresReply ([MRESULT](#)) - returns
Message-return data.

WinDispatchMsg - Remarks

This function is equivalent to using the [WinSendMsg](#) function with the parameters corresponding to those in *pqmsgMsg*.

The time and pointer position information within *pqmsgMsg* can be obtained by the window procedure with the [WinQueryMsgTime](#) and [WinQueryMsgPos](#) functions.

mresReply is the value returned by the invoked window procedure. For standard window classes, the values of *mresReply* are documented with the message definitions;

WinDispatchMsg - Example Code

This example, after uses WinDispatchMsg within a WinGetMsg loop to dispatch window messages to a window procedure.

```
#define INCL_WINMESSAGEGR      /* Window Message Functions */
#define INCL_WINWINDOWMGR     /* Window Manager Functions */
#include <os2.h>

HAB      hab;                /* anchor-block handle */
HMQ      hmq;                /* message queue handle */
QMSG     qmsg;               /* message */

hab = WinInitialize(0);      /* initialize PM */

hmq = WinCreateMsgQueue(hab, 0); /* create default size queue */

/*
.
.  initialize windows
.
*/

/* get and dispatch messages from queue */
while (WinGetMsg(hab, &qmsg, 0, 0, 0))
    WinDispatchMsg(hab, &qmsg);
```

WinDlgBox

WinDlgBox - Syntax

This function loads and processes a modal dialog window and returns the result value established by the [WinDismissDlg](#) call.

```
#define INCL_WINDIALOGS /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HWND      hwndParent;        /* Parent-window handle of the created dialog window. */
HWND      hwndOwner;         /* Requested owner-window handle of the created dialog window. */
```

```

PFNWP      pfnDlgProc;      /* Dialog procedure for the created dialog window. */
HMODULE     hmod;           /* Resource identity containing the dialog template. */
ULONG      idDlg;          /* Dialog-template identity within the resource file. */
PVOID      pCreateParams;  /* Pointer to application-defined data area. */
ULONG      ulResult;       /* Reply value. */

ulResult = WinDlgBox(hwndParent, hwndOwner,
                    pfnDlgProc, hmod, idDlg, pCreateParams);

```

WinDlgBox Parameter - hwndParent

hwndParent ([HWND](#)) - input

Parent-window handle of the created dialog window.

HWND_DESKTOP

The desktop window

HWND_OBJECT

Object window

Other

Specified window.

WinDlgBox Parameter - hwndOwner

hwndOwner ([HWND](#)) - input

Requested owner-window handle of the created dialog window.

The actual owner window is calculated using the algorithm specified in the description of the [WinLoadDlg](#) function.

WinDlgBox Parameter - pfnDlgProc

pfnDlgProc ([PFNWP](#)) - input

Dialog procedure for the created dialog window.

WinDlgBox Parameter - hmod

hmod ([HMODULE](#)) - input

Resource identity containing the dialog template.

NULLHANDLE

Use the application's .EXE file.

Other

Module handle returned from the DosLoadModule or DosQueryModuleHandle call.

WinDlgBox Parameter - idDlg

idDlg ([ULONG](#)) - input

Dialog-template identity within the resource file.

It is also used as the identity of the created dialog window. Is must be greater or equal to 0 and less or equal to 0xFFFF.

WinDlgBox Parameter - pCreateParams

pCreateParams ([PVOID](#)) - input

Pointer to application-defined data area.

This is passed to the dialog procedure in the [WM_INITDLG](#) message.

This parameter MUST be a pointer rather than a long.

WinDlgBox Return Value - ulResult

ulResult ([ULONG](#)) - returns

Reply value.

Value established by the [WinDismissDlg](#) call or DID_ERROR if an error occurs.

WinDlgBox - Parameters

hwndParent ([HWND](#)) - input

Parent-window handle of the created dialog window.

HWND_DESKTOP

The desktop window

HWND_OBJECT

Object window

Other

Specified window.

hwndOwner ([HWND](#)) - input

Requested owner-window handle of the created dialog window.

The actual owner window is calculated using the algorithm specified in the description of the [WinLoadDlg](#) function.

pfnDlgProc ([PFNWP](#)) - input
Dialog procedure for the created dialog window.

hmod ([HMODULE](#)) - input
Resource identity containing the dialog template.

NULLHANDLE
Use the application's .EXE file.
Other
Module handle returned from the [DosLoadModule](#) or [DosQueryModuleHandle](#) call.

idDlg ([ULONG](#)) - input
Dialog-template identity within the resource file.

It is also used as the identity of the created dialog window. Its must be greater or equal to 0 and less or equal to 0xFFFF.

pCreateParams ([PVOID](#)) - input
Pointer to application-defined data area.

This is passed to the dialog procedure in the [WM_INITDLG](#) message.

This parameter MUST be a pointer rather than a long.

ulResult ([ULONG](#)) - returns
Reply value.

Value established by the [WinDismissDlg](#) call or [DID_ERROR](#) if an error occurs.

WinDlgBox - Remarks

The use of parameters to this function are the same as those of the [WinLoadDlg](#) function.

This function should not be used while pointing device capture is set (see [WinSetCapture](#)).

This function does not return until [WinDismissDlg](#) is called.

This function is equivalent to:

```
WinLoadDlg (., ., ., ., ., ., ., dlg);  
WinProcessDlg (dlg, result);  
WinDestroyWindow (dlg, success);  
return (result);
```

and the remarks documented under these calls also apply.

If a dialog template (typically compiled using the resource compiler) references another resource (for example an icon resource for an icon static control), this function always searches for that resource in the .EXE file. If an application wishes to keep resources referenced by a dialog template in a .DLL library, these resources must be loaded by an explicit function call during the processing of the [WM_INITDLG](#) message.

This can be considered to be a customizable "read from screen" call. The caller supplies a data buffer (the *pCreateParams* parameter), filled with initial values. It receives a return code which indicates whether the data in the buffer has been updated and validated, or whether the end user cancelled the dialog. The end user interface is encapsulated within the dialog window. The dialog template provides a view of the current state of the data buffer, the dialog procedure defines how the user can change the data. The caller need know nothing about the details of the end user interface. It makes a single "read from screen" call and continues with its work.

Note: If a dialog box or a message box is up for a window, and the parent or owner of that window is destroyed, the code following the [WinDlgBox](#) or [WinMessageBox](#) call is executed even though the parent/owner window no longer exists. This can result in accessing data that no longer exists; especially data referenced in the window words. Therefore, it is extremely important to determine the state of your child-window procedure after this function returns. The most straightforward method for doing this is to call [WinQueryWindowPtr](#) to get a pointer to the window words. If the returned pointer is NULL, then you should exit immediately. Should this be the case, the bottom-up rule (that is, the child window gets [WM_DESTROY](#) messages first, then the parent window) still applies, and it becomes the child window procedure's responsibility to exit gracefully.

WinDlgBox - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)

An invalid window handle was specified.

PMERR_INVALID_INTEGER_ATOM (0x1016)

The specified atom is not a valid integer atom.

PMERR_INVALID_ATOM_NAME (0x1015)

An invalid atom name string was passed.

PMERR_ATOM_NAME_NOT_FOUND (0x1017)

The specified atom name is not in the atom table.

PMERR_RESOURCE_NOT_FOUND (0x100A)

The specified resource identity could not be found.

WinDlgBox - Example Code

This example processes an application-defined message (IDM_OPEN) and calls WinDlgBox to load a dialog box.

```
#define IDD_OPEN 1
#define INCL_WINDIALOGS          /* Window Dialog Mgr Functions */
#include <os2.h>

HWND    hwndFrame;                /* frame window handle */
PFNWP   OpenDlg;

case IDM_OPEN:
```

```

if (WinDlgBox(HWND_DESKTOP,
    hwndFrame,      /* handle of the owner      */
    OpenDlg,        /* dialog procedure address */
    NULLHANDLE,     /* location of dialog resource */
    IDD_OPEN,       /* resource identifier      */
    NULL)) {        /* application-specific data */
    .
. /* code executed if dialog box returns TRUE */
.
}

```

WinDrawBitmap

WinDrawBitmap - Syntax

This function draws a bit map using the current image colors and mixes.

```

#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HPS      hpsDst; /* Handle of presentation space in which the bit map is drawn. */
HBITMAP  hbm;    /* Bit-map handle. */
PRECTL   pwrcSrc; /* Subrectangle of bit map to be drawn. */
PPOINTL  pptlDst; /* Bit-map destination. */
LONG     clrFore; /* Foreground color. */
LONG     clrBack; /* Background color. */
ULONG    fl;      /* Flags that determine how the bit map is drawn. */
BOOL     rc;      /* Success indicator. */

rc = WinDrawBitmap(hpsDst, hbm, pwrcSrc, pptlDst,
    clrFore, clrBack, fl);

```

WinDrawBitmap Parameter - hpsDst

hpsDst ([HPS](#)) - input
Handle of presentation space in which the bit map is drawn.

WinDrawBitmap Parameter - hbm

hbm ([HBITMAP](#)) - input
Bit-map handle.

WinDrawBitmap Parameter - pwrcSrc

pwrcSrc ([PRECTL](#)) - input
Subrectangle of bit map to be drawn.

Note: The value of each field in this structure must be in the range -32 768 through 32 768. The data type [WRECT](#) can also be used, if supported by the language.

- | | |
|-------|--|
| NULL | The whole of the bit map is drawn |
| Other | The whole of the bit map is not drawn. |

WinDrawBitmap Parameter - pptIDst

pptIDst ([PPOINTL](#)) - input
Bit-map destination.

The bottom left corner of the bit-map destination is specified in device coordinates.

If DBM_STRETCH is set in *hbm*, this parameter is used as a pointer to a [RECTL](#) data structure that contains the coordinates of the rectangle into which the source bit map is to be drawn. In this situation, *pptIDst* should be treated as a PRECTL datatype.

WinDrawBitmap Parameter - clrFore

clrFore ([LONG](#)) - input
Foreground color.

This is used if *hbm* refers to a monochrome bit map. In this instance, bit-map bits that are set to 1 are drawn using *clrFore*. Ignored if DBM_IMAGEATTRS is specified.

WinDrawBitmap Parameter - clrBack

clrBack (**LONG**) - input
Background color.

This is used if *hbm* refers to a monochrome bit map. In this instance, bit-map bits that are set to zero are drawn using *clrBack*. Ignored if DBM_IMAGEATTRS is specified.

WinDrawBitmap Parameter - fl

fl (**ULONG**) - input
Flags that determine how the bit map is drawn.

- DBM_NORMAL Draw the bit map normally using ROP_SRCCOPY, as defined in GpiBitBlt.
- DBM_INVERT Draw the bit map inverted using ROP_NOTSRCCOPY, as defined in GpiBitBlt.
- DBM_STRETCH *pptlDst* is used to point to a **RECTL** data structure representing a rectangle in the destination presentation space, into which the bit map will be stretched or compressed. If compression is required, some rows and columns of the bit map are eliminated.
- DBM_HALFTONE Use the OR operator to combine the bit map with an alternating pattern of ones or zeros before drawing it. It can be used with either DBM_NORMAL or DBM_INVERT.
- DBM_IMAGEATTRS If this is specified, color conversion of monochrome bit maps is done by using the image attributes.

WinDrawBitmap Return Value - rc

rc (**BOOL**) - returns
Success indicator.

- TRUE Successful completion
- FALSE Error occurred.

WinDrawBitmap - Parameters

hpsDst (**HPS**) - input
Handle of presentation space in which the bit map is drawn.

hbm ([HBITMAP](#)) - input
Bit-map handle.

pwrcSrc ([PRECTL](#)) - input
Subrectangle of bit map to be drawn.

Note: The value of each field in this structure must be in the range -32 768 through 32 768.
The data type [WRECT](#) can also be used, if supported by the language.

NULL
The whole of the bit map is drawn

Other
The whole of the bit map is not drawn.

pptlDst ([PPOINTL](#)) - input
Bit-map destination.

The bottom left corner of the bit-map destination is specified in device coordinates.

If DBM_STRETCH is set in *fl*, this parameter is used as a pointer to a [RECTL](#) data structure that contains the coordinates of the rectangle into which the source bit map is to be drawn. In this situation, *pptlDst* should be treated as a PRECTL datatype.

clrFore ([LONG](#)) - input
Foreground color.

This is used if *hbm* refers to a monochrome bit map. In this instance, bit-map bits that are set to 1 are drawn using *clrFore*. Ignored if DBM_IMAGEATTRS is specified.

clrBack ([LONG](#)) - input
Background color.

This is used if *hbm* refers to a monochrome bit map. In this instance, bit-map bits that are set to zero are drawn using *clrBack*. Ignored if DBM_IMAGEATTRS is specified.

fl ([ULONG](#)) - input
Flags that determine how the bit map is drawn.

DBM_NORMAL
Draw the bit map normally using ROP_SRCCOPY, as defined in GpiBitBlt.

DBM_INVERT
Draw the bit map inverted using ROP_NOTSRCCOPY, as defined in GpiBitBlt.

DBM_STRETCH
pptlDst is used to point to a [RECTL](#) data structure representing a rectangle in the destination presentation space, into which the bit map will be stretched or compressed. If compression is required, some rows and columns of the bit map are eliminated.

DBM_HALFTONE
Use the OR operator to combine the bit map with an alternating pattern of ones or zeros before drawing it. It can be used with either DBM_NORMAL or DBM_INVERT.

DBM_IMAGEATTRS
If this is specified, color conversion of monochrome bit maps is done by using the image attributes.

rc ([BOOL](#)) - returns
Success indicator.

TRUE
Successful completion

FALSE
Error occurred.

WinDrawBitmap - Remarks

This function should only be used in draw mode (DM_DRAW) to a screen device context (see "GpiSetDrawingMode" in the *Graphics*

Programming Interface Programming Reference). The presentation space handle can be to either a micro-presentation space or a normal presentation space (see "GpiCreatePS" in the *Graphics Programming Interface Programming Reference*).

If *hbm* refers to a color bit map, no color conversion is performed.

The current position in the presentation space is not changed by this function.

WinDrawBitmap - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_FLAG (0x1019)

An invalid bit was set for a parameter. Use constants defined by PM for options, and do not set any reserved bits.

PMERR_HBITMAP_BUSY (0x2032)

An internal bit map busy error was detected. The bit map was locked by one thread during an attempt to access it from another thread.

WinDrawBitmap - Example Code

This example uses WinDrawBitmap to draw the system-defined menu check mark bit map in response to the user selecting a menu item (WM_MENUSELECT), using the bit-map handle returned by WinGetSysBitmap.

```
#define INCL_WINWINDOWMGR      /* Window Manager Functions */
#define INCL_WINPOINTERS      /* Window Pointer Functions */
#define INCL_WINMESSAGEGR     /* Window Message Functions */
#define INCL_WINMENUS         /* Window Menu Functions */

#include <os2.h>

HPS    hps;          /* presentation-space handle */
HBITMAP hbmCheck;    /* check mark bit-map handle */
HWND   hwndMenu;     /* menu handle */
USHORT usItemId;     /* menu item id */
RECT   rcItem;       /* item border rectangle */
MPARAM mpParam1;     /* Parameter 1 (menu item id) */
MPARAM mpParam2;     /* Parameter 2 (menu handle) */

case WM_CREATE:
    /* obtain check mark bit-map handle */
```

```

        hbmCheck = WinGetSysBitmap(HWND_DESKTOP, SBMP_MENUCHECK);

case WM_MENUSELECT:
    usItemId = SHORT1FROMMP(mpParam1);
    hwndMenu = HWNDFROMMP(mpParam2);

    /* get rectangle of selected item */
    WinSendMsg(hwndMenu,
        MM_QUERYITEMRECT,
        MPFROM2SHORT(usItemId, TRUE),
        MPFROMP(&rclItem));

    /* draw the check mark in the lower left corner of item's
       rectangle */
    if (hbmCheck != NULL)
    {
        WinDrawBitmap(hps,
            hbmCheck,          /* check mark          */
            NULL,             /* draw whole bit map  */
            (PPOINTL)&rclItem, /* bit-map destination */
            0L,               /* ignored since color  */
            0L,               /* bit map             */
            DBM_NORMAL);      /* draw normal size     */
    }
}

```

WinDrawBorder

WinDrawBorder - Syntax

This function draws the borders and interior of a rectangle.

```

#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HPS      hps;          /* Presentation-space handle. */
PRECTL   prcl;         /* Bounding rectangle for the border. */
LONG     cx;           /* Width of border rectangle vertical sides. */
LONG     cy;           /* Width of border rectangle horizontal sides. */
LONG     clrFore;      /* Color of edge of border. */
LONG     clrBack;      /* Color of interior of border. */
ULONG    flCmd;        /* Flags controlling the way in which the border is drawn. */
BOOL     rc;           /* Success indicator. */

```

```
rc = WinDrawBorder(hps, prcl, cx, cy, clrFore,  
                  clrBack, flCmd);
```

WinDrawBorder Parameter - hps

hps ([HPS](#)) - input
Presentation-space handle.

WinDrawBorder Parameter - prcl

prcl ([PRECTL](#)) - input
Bounding rectangle for the border.

The rectangle is in device coordinates.

The border is drawn within the rectangle. Along the bottom and left edges of the rectangle, the edges of the border coincide with the rectangle edges. Along the top and right edges of the rectangle, the border is drawn one device unit inside the rectangle edges.

Note: The value of each field in this structure must be in the range -32 768 through 32 768. The data type [WRECT](#) can also be used, if supported by the language.

WinDrawBorder Parameter - cx

cx ([LONG](#)) - input
Width of border rectangle vertical sides.

This is the width of the left and right sides in device coordinates.

WinDrawBorder Parameter - cy

cy ([LONG](#)) - input
Width of border rectangle horizontal sides.

This is the width of the top and bottom sides in device coordinates.

WinDrawBorder Parameter - clrFore

clrFore ([LONG](#)) - input
Color of edge of border.

Not used if DB_AREATTRS is specified.

WinDrawBorder Parameter - clrBack

clrBack ([LONG](#)) - input
Color of interior of border.

Not used if DB_AREATTRS is specified.

WinDrawBorder Parameter - flCmd

flCmd ([ULONG](#)) - input
Flags controlling the way in which the border is drawn.

Some of the DB_* flags are mutually exclusive. Only one of these four can be significant:

- DB_PATCOPY (default)
- DB_PATINVERT
- DB_DESTINVERT
- DB_AREAMIXMODE.

Possible values are described in the following list:

DB_ROP	A group of flags that specify the mix to be used, for both the border and the interior.
DB_PATCOPY	Use the ROP_PATCOPY raster operation (see "GpiBitBlt" in the <i>Graphics Programming Interface Programming Reference</i>). This is a copy of the pattern to the destination.
DB_PATINVERT	Use the ROP_PATINVERT raster operation (see "GpiBitBlt" in the <i>Graphics Programming Interface Programming Reference</i>). This is an exclusive-OR of the pattern with the destination.
DB_DESTINVERT	Use the ROP_DESTINVERT raster operation (see "GpiBitBlt" in the <i>Graphics Programming Interface Programming Reference</i>). This inverts the destination.
DB_AREAMIXMODE	Map the current area foreground mix attribute into a BitBlt raster operation (see "GpiBitBlt" in the <i>Graphics Programming Interface Programming Reference</i>). The area background mix mode is ignored.
DB_INTERIOR	The area contained within the given rectangle, and not included within the borders (as given by <i>cx</i> and <i>cy</i>), is drawn.
DB_AREATTRS	

- If this is specified:

For any border, the pattern used is the pattern as currently defined in the area attribute.

For any interior, the pattern used is the same as if GpiSetAttrs for the area attributes is made with the background color of the area attribute being passed for the foreground color, and the foreground color of the area attribute being passed as the background color.

- If this is not specified (default):

For any border, the pattern used is the same as if GpiSetAttrs for the area attributes is made with a foreground color of *clrFore*, and a background color of *clrBack*.

For any interior, the pattern used is the same as if GpiSetAttrs for the area attributes is made with a foreground color of *clrBack*, and a background color of *clrFore*.

DB_STANDARD

cx and *cy* are multiplied by the system SV_CXBORDER and SV_CYBORDER constants to produce the widths of the vertical and horizontal sides of the border.

DB_DLGBOARDER

A standard dialog border is drawn, in the active titlebar color if DB_PATCOPY is specified, or the inactive titlebar color if DB_PATINVERT is specified. Other DB_ROP options, and DB_AREAATTRS, are ignored.

DB_ROP and DB_AREAATTRS are also ignored for the interior. The interior is drawn in the color specified by *clrBack*.

WinDrawBorder Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE

Successful completion

FALSE

Error occurred.

WinDrawBorder - Parameters

hps (**HPS**) - input
Presentation-space handle.

prcl (**PRECTL**) - input
Bounding rectangle for the border.

The rectangle is in device coordinates.

The border is drawn within the rectangle. Along the bottom and left edges of the rectangle, the edges of the border coincide with the rectangle edges. Along the top and right edges of the rectangle, the border is drawn one device unit inside the rectangle edges.

Note: The value of each field in this structure must be in the range -32 768 through 32 768. The data type **WRECT** can also be used, if supported by the language.

cx (**LONG**) - input
Width of border rectangle vertical sides.

This is the width of the left and right sides in device coordinates.

cy (**LONG**) - input
Width of border rectangle horizontal sides.

This is the width of the top and bottom sides in device coordinates.

clrFore ([LONG](#)) - input
Color of edge of border.

Not used if DB_AREAATTRS is specified.

clrBack ([LONG](#)) - input
Color of interior of border.

Not used if DB_AREAATTRS is specified.

flCmd ([ULONG](#)) - input
Flags controlling the way in which the border is drawn.

Some of the DB_* flags are mutually exclusive. Only one of these four can be significant:

- DB_PATCOPY (default)
- DB_PATINVERT
- DB_DESTINVERT
- DB_AREAMIXMODE.

Possible values are described in the following list:

DB_ROP
A group of flags that specify the mix to be used, for both the border and the interior.

DB_PATCOPY
Use the ROP_PATCOPY raster operation (see "GpiBitBlt" in the *Graphics Programming Interface Programming Reference*). This is a copy of the pattern to the destination.

DB_PATINVERT
Use the ROP_PATINVERT raster operation (see "GpiBitBlt" in the *Graphics Programming Interface Programming Reference*). This is an exclusive-OR of the pattern with the destination.

DB_DESTINVERT
Use the ROP_DESTINVERT raster operation (see "GpiBitBlt" in the *Graphics Programming Interface Programming Reference*). This inverts the destination.

DB_AREAMIXMODE
Map the current area foreground mix attribute into a Bitblt raster operation (see "GpiBitBlt" in the *Graphics Programming Interface Programming Reference*). The area background mix mode is ignored.

DB_INTERIOR
The area contained within the given rectangle, and not included within the borders (as given by *cx* and *cy*), is drawn.

DB_AREAATTRS

- If this is specified:

For any border, the pattern used is the pattern as currently defined in the area attribute.

For any interior, the pattern used is the same as if GpiSetAttrs for the area attributes is made with the background color of the area attribute being passed for the foreground color, and the foreground color of the area attribute being passed as the background color.
- If this is not specified (default):

For any border, the pattern used is the same as if GpiSetAttrs for the area attributes is made with a foreground color of *clrFore*, and a background color of *clrBack*.

For any interior, the pattern used is the same as if GpiSetAttrs for the area attributes is made with a foreground color of *clrBack*, and a background color of *clrFore*.

DB_STANDARD
cx and *cy* are multiplied by the system SV_CXBORDER and SV_CYBORDER constants to produce the widths of the vertical and horizontal sides of the border.

DB_DLGBORDER
A standard dialog border is drawn, in the active titlebar color if DB_PATCOPY is specified, or the inactive titlebar color if DB_PATINVERT is specified. Other DB_ROP options, and DB_AREAATTRS, are ignored.

DB_ROP and DB_AREATTRS are also ignored for the interior. The interior is drawn in the color specified by *clrBack*.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinDrawBorder - Remarks

A border is a rectangular frame, normally used around the edge of a window.

This function should only be used in draw mode (DM_DRAW), to a screen device context; *hps* can be either a micro-presentation space or a normal presentation space (see "GpiCreatePS" in the *Graphics Programming Interface Programming Reference*). DB_DESTINVERT inverts the destination.

If DB_AREAMIXMODE is given, the foreground mix mode from the area attribute is mapped into an equivalent ROP_ value (see "GpiBitBlt" in the *Graphics Programming Interface Programming Reference*). The area background mix mode is ignored.

Either or both *cx* or *cy* can be zero. If both are zero, the interior is still drawn. If either the x borders overlap or the y borders overlap, the border is drawn as a single rectangle with no interior.

WinDrawBorder - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_FLAG (0x1019)

An invalid bit was set for a parameter. Use constants defined by PM for options, and do not set any reserved bits.

PMERR_INV_DRAW_BORDER_OPTION (0x2068)

An invalid option parameter was specified with WinDrawBorder.

WinDrawBorder - Example Code

This example uses WinDrawBorder to draw the border (width of 5) and interior of a 300x200 rectangle anchored at (0,0), and using the area's current attributes for both the border and interior colors.

```
#define INCL_WINWINDOWMGR      /* Window Manager Functions */
#include <os2.h>

HPS    hps;          /* presentation-space handle */
BOOL    fSuccess;     /* success indicator */
RECTL   prclRectangle={0,0,300,200}; /* border rectangle */
LONG    lVertSideWidth=5; /* Width of border rectangle vertical
                           sides */
LONG    lHorizSideWidth=5; /* Width of border rectangle horizontal
                           sides */
ULONG    flCmd;       /* draw flags */

/* use current area attributes */
flCmd = DB_AREAATTRS;

fSuccess = WinDrawBorder(hps, &prclRectangle, lVertSideWidth,
                        lHorizSideWidth, 0L, 0L, flCmd);
```

WinDrawPointer

WinDrawPointer - Syntax

This function draws a pointer in the passed *hps* at the passed coordinates [*lx*, *ly*].

```
#define INCL_WINPOINTERS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HPS    hps;          /* Presentation-space handle into which the pointer is drawn. */
LONG    lx;          /* x-coordinate at which to draw the pointer, in device coordinates. */
LONG    ly;          /* y-coordinate at which to draw the pointer, in device coordinates. */
HPOINTER hpPtrPointer; /* Pointer handle. */
ULONG    ulHalftone;  /* Shading control with which to draw the pointer. */
BOOL    rc;          /* Success indicator. */

rc = WinDrawPointer(hps, lx, ly, hpPtrPointer,
                    ulHalftone);
```

WinDrawPointer Parameter - hps

hps ([HPS](#)) - input

Presentation-space handle into which the pointer is drawn.

This can be either a micro presentation space or a normal presentation space (see "GpiCreatePS" in the *Graphics Programming Interface Programming Reference*).

WinDrawPointer Parameter - lx

lx ([LONG](#)) - input

x-coordinate at which to draw the pointer, in device coordinates.

WinDrawPointer Parameter - ly

ly ([LONG](#)) - input

y-coordinate at which to draw the pointer, in device coordinates.

WinDrawPointer Parameter - hptrPointer

hptrPointer ([HPOINTER](#)) - input

Pointer handle.

The pointer should be loaded using [WinLoadPointer](#), [WinCreatePointer](#), or [WinCreatePointerIndirect](#).

WinDrawPointer Parameter - ulHalftone

ulHalftone ([ULONG](#)) - input

Shading control with which to draw the pointer.

DP_NORMAL

As it normally appears.

DP_HALFTONED

With a halftone pattern where black normally appears.

DP_INVERTED	Inverted, black for white and white for black.
DP_MINIICON	Bit map of a mini icon.

WinDrawPointer Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Function failed.

WinDrawPointer - Parameters

hps (**HPS**) - input
Presentation-space handle into which the pointer is drawn.

This can be either a micro presentation space or a normal presentation space (see "GpiCreatePS" in the *Graphics Programming Interface Programming Reference*).

lx (**LONG**) - input
x-coordinate at which to draw the pointer, in device coordinates.

ly (**LONG**) - input
y-coordinate at which to draw the pointer, in device coordinates.

hptrPointer (**HPOINTER**) - input
Pointer handle.

The pointer should be loaded using [WinLoadPointer](#), [WinCreatePointer](#), or [WinCreatePointerIndirect](#).

ulHalftone (**ULONG**) - input
Shading control with which to draw the pointer.

DP_NORMAL	As it normally appears.
DP_HALFTONED	With a halftone pattern where black normally appears.
DP_INVERTED	Inverted, black for white and white for black.
DP_MINIICON	Bit map of a mini icon.

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Function failed.

WinDrawPointer - Remarks

This function should only be used in draw mode (DM_DRAW) to a screen device context.

WinDrawPointer - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HPTR (0x101B)
An invalid pointer handle was specified.

PMERR_INVALID_FLAG (0x1019)
An invalid bit was set for a parameter. Use constants defined by PM for options, and do not set any reserved bits.

WinDrawPointer - Example Code

This example draws a bit map pointer, created by either WinCreatePointer or WinCreatePointerIndirect, in response to a paint message (WM_PAINT).

```
#define INCL_WINPOINTERS      /* Window Pointer Functions */
#define INCL_GPIBITMAPS      /* Graphics bit-map functions */
#include <os2.h>

HPS    hps;          /* presentation-space handle */
HWND   hwnd;         /* window handle */
```

```

HPOINTER  hptr;           /* bit-map pointer handle          */
HBITMAP   hbm;           /* bit-map handle          */
BOOL      fSuccess;       /* success indicator       */
ULONG     ulHalftone=DP_NORMAL; /* draw with normal shading */

case WM_CREATE:
    hps = WinBeginPaint(hwnd, NULLHANDLE, NULL);
    hbm = GpiLoadBitmap(hps, 0L, IDP_BITMAP, 64L, 64L);
    WinEndPaint(hps);

    hptr = WinCreatePointer(HWND_DESKTOP, hbm,
                           TRUE, /* use true (system) pointer */
                           0, 0); /* hot spot offset (0,0) */

case WM_PAINT:
    hps = WinBeginPaint(hwnd, NULLHANDLE, NULL);
    fSuccess = WinDrawPointer(hps, 50, 50, hptr, ulHalftone);
    WinEndPaint(hps);

WinDrawText

WinDrawText - Syntax

This function draws a single line of formatted text into a specified rectangle.

```

#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HPS      hps;           /* Presentation-space handle. */
LONG     cchText;       /* Count of the number of characters in the string. */
PCH      lpchText;     /* Character string to be drawn. */
PRECTL   prcl;         /* Text rectangle. */
LONG     clrFore;       /* Foreground color. */
LONG     clrBack;       /* Background color. */
ULONG     flCmd;        /* An array of flags that determines how the text is drawn. */
LONG     lChars;        /* Count of characters drawn within the rectangle. */

lChars = WinDrawText(hps, cchText, lpchText,
                    prcl, clrFore, clrBack, flCmd);

```

WinDrawText Parameter - hps

hps ([HPS](#)) - input
Presentation-space handle.

WinDrawText Parameter - cchText

cchText ([LONG](#)) - input
Count of the number of characters in the string.

This parameter must be greater or equal to -1L.

-1L The string is null-terminated and its length is to be calculated by this function.

Other Count of the number of characters in the string.

WinDrawText Parameter - lpchText

lpchText ([PCH](#)) - input
Character string to be drawn.

A carriage-return or line-feed character always terminates a line. If the length of a line is less than *cchText* (the string is divided into more than one line) each line is terminated by either of the mentioned characters.

WinDrawText Parameter - prcl

prcl ([PRECTL](#)) - in/out
Text rectangle.

Rectangle within which the text is to be formatted, in world coordinates. Points on the boundary of this rectangle are deemed to be inside the rectangle.

On input, this rectangle is the desired rectangle in which the text is to be drawn.

On output, the height of the rectangle is modified to the actual size needed to draw the given text string. The return value is only of interest in the instance where DT_QUERYEXTENT is set in *flCmd*.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) can also be used, if supported by the language.

WinDrawText Parameter - clrFore

clrFore ([LONG](#)) - input
Foreground color.

Ignored if DT_TEXTATTRS is specified.

WinDrawText Parameter - clrBack

clrBack ([LONG](#)) - input
Background color.

The background is drawn with the current background mix. The default is BM_LEAVEALONE, that is, *clrBack* is ignored unless GpiSetBackMix is called.

The background rectangle is the rectangle that bounds the text; it is not the input parameter rectangle.

This parameter is ignored if DT_TEXTATTRS is specified.

WinDrawText Parameter - flCmd

flCmd ([ULONG](#)) - input
An array of flags that determines how the text is drawn.

Some of the DT_ flags are mutually exclusive. Only **one** from each of these groups is significant:

- DT_LEFT (default), DT_CENTER, DT_RIGHT
- DT_TOP (default), DT_VCENTER, DT_BOTTOM.

When mutually-exclusive flags are used together, the function gives indeterminate results.

If DT_HALFTONE, DT_ERASERECT, or DT_MNEMONIC is used, the presentation space must be in PU_PELS units.

DT_LEFT
Left-justify the text.

DT_CENTER
Center the text.

DT_RIGHT
Right-justify the text.

DT_VCENTER
Vertically center the text.

DT_TOP
Top-justify the text.

DT_BOTTOM
Bottom-justify the text.

DT_HALFTONE
Halftone the text display.

DT_MNEMONIC
If a mnemonic prefix character is encountered, the next character is drawn with mnemonic emphasis.

DT_QUERYEXTENT

The height *prc* is changed to a rectangle that bounds the string if it were drawn with WinDrawText.

DT_WORDBREAK

Only words that fit completely within the supplied rectangle are drawn. A *word* is defined as:

Any number of leading spaces followed by one or more visible characters and terminated by a space, carriage return, or line-feed character.

When calculating whether a particular word fits within the given rectangle, this function does not consider the trailing blanks. Only the length of the visible part of the word is tested against the right edge of the rectangle.

Also, note that this function always tries to draw at least one word, even if that word does not fit in the passed rectangle. This is so that progress is always made when drawing multiline text.

DT_EXTERNALLEADING

This flag causes the "external leading" value for the current font to be added to the bottom of the bounding rectangle before returning. It has an effect only when both DT_TOP and DT_QUERYEXTENT are also specified.

DT_TEXTATTRS

If this is specified, text is drawn using the character foreground and background colors of the presentation space, and *clrFore* and *clrBack* are ignored.

DT_ERASERECT

If this is specified, the rectangle defined by *prc* is erased before drawing the text. Otherwise, the background of the characters themselves can be erased if the character background mix (see "GpiSetAttrs" and "GpiSetBackMix" in the *Graphics Programming Interface Programming Reference*) is set to BM_OVERPAINT.

DT_UNDERSCORE

Underscore the characters. See FATTR_SEL_UNDERSCORE in the [FATTRS](#) datatype.

DT_STRIKEOUT

Overstrike the characters. See FATTR_SEL_STRIKEOUT in the [FATTRS](#) datatype.

WinDrawText Return Value - IChars

IChars ([LONG](#)) - returns

Count of characters drawn within the rectangle.

If DT_WORDBREAK is specified, this parameter returns the number of characters displayed. However, if the first word of the string does not fit in the rectangle, this parameter reflects the fact that the entire word is drawn.

If DT_WORDBREAK is **not** specified, the count returned is the full length of the string regardless of how much fits into the bounding rectangle.

0

Error occurred

Other

Count of characters drawn within the rectangle.

WinDrawText - Parameters

hps ([HPS](#)) - input

Presentation-space handle.

cchText ([LONG](#)) - input

Count of the number of characters in the string.

This parameter must be greater or equal to -1L.

-1L

The string is null-terminated and its length is to be calculated by this function.

Other

Count of the number of characters in the string.

lpchText (**PCH**) - input

Character string to be drawn.

A carriage-return or line-feed character always terminates a line. If the length of a line is less than *achText* (the string is divided into more than one line) each line is terminated by either of the mentioned characters.

prcl (**PRECTL**) - in/out

Text rectangle.

Rectangle within which the text is to be formatted, in world coordinates. Points on the boundary of this rectangle are deemed to be inside the rectangle.

On input, this rectangle is the desired rectangle in which the text is to be drawn.

On output, the height of the rectangle is modified to the actual size needed to draw the given text string. The return value is only of interest in the instance where DT_QUERYEXTENT is set in *flCmd*.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type **WRECT** can also be used, if supported by the language.

clrFore (**LONG**) - input

Foreground color.

Ignored if DT_TEXTATTRS is specified.

clrBack (**LONG**) - input

Background color.

The background is drawn with the current background mix. The default is BM_LEAVEALONE, that is, *clrBack* is ignored unless GpiSetBackMix is called.

The background rectangle is the rectangle that bounds the text; it is not the input parameter rectangle.

This parameter is ignored if DT_TEXTATTRS is specified.

flCmd (**ULONG**) - input

An array of flags that determines how the text is drawn.

Some of the DT_ flags are mutually exclusive. Only **one** from each of these groups is significant:

- DT_LEFT (default), DT_CENTER, DT_RIGHT
- DT_TOP (default), DT_VCENTER, DT_BOTTOM.

When mutually-exclusive flags are used together, the function gives indeterminate results.

If DT_HALFTONE, DT_ERASERECT, or DT_MNEMONIC is used, the presentation space must be in PU_PELS units.

DT_LEFT

Left-justify the text.

DT_CENTER

Center the text.

DT_RIGHT

Right-justify the text.

DT_VCENTER

Vertically center the text.

DT_TOP

Top-justify the text.

DT_BOTTOM

Bottom-justify the text.

DT_HALFTONE

Halftone the text display.

DT_MNEMONIC

If a mnemonic prefix character is encountered, the next character is drawn with mnemonic emphasis.

DT_QUERYEXTENT

The height *prc* is changed to a rectangle that bounds the string if it were drawn with WinDrawText.

DT_WORDBREAK

Only words that fit completely within the supplied rectangle are drawn. A *word* is defined as:

Any number of leading spaces followed by one or more visible characters and terminated by a space, carriage return, or line-feed character.

When calculating whether a particular word fits within the given rectangle, this function does not consider the trailing blanks. Only the length of the visible part of the word is tested against the right edge of the rectangle.

Also, note that this function always tries to draw at least one word, even if that word does not fit in the passed rectangle. This is so that progress is always made when drawing multiline text.

DT_EXTERNALLEADING

This flag causes the "external leading" value for the current font to be added to the bottom of the bounding rectangle before returning. It has an effect only when both DT_TOP and DT_QUERYEXTENT are also specified.

DT_TEXTATTRS

If this is specified, text is drawn using the character foreground and background colors of the presentation space, and *clrFore* and *clrBack* are ignored.

DT_ERASERECT

If this is specified, the rectangle defined by *prc* is erased before drawing the text. Otherwise, the background of the characters themselves can be erased if the character background mix (see "GpiSetAttrs" and "GpiSetBackMix" in the *Graphics Programming Interface Programming Reference*) is set to BM_OVERPAINT.

DT_UNDERSCORE

Underscore the characters. See FATTR_SEL_UNDERSCORE in the [FATTRS](#) datatype.

DT_STRIKEOUT

Overstrike the characters. See FATTR_SEL_STRIKEOUT in the [FATTRS](#) datatype.

IChars ([LONG](#)) - returns

Count of characters drawn within the rectangle.

If DT_WORDBREAK is specified, this parameter returns the number of characters displayed. However, if the first word of the string does not fit in the rectangle, this parameter reflects the fact that the entire word is drawn.

If DT_WORDBREAK is **not** specified, the count returned is the full length of the string regardless of how much fits into the bounding rectangle.

0

Error occurred

Other

Count of characters drawn within the rectangle.

WinDrawText - Remarks

Text is always drawn in the current font with the current foreground and background mix modes.

This function must only be used in draw mode (DM_DRAW), to a screen device context; *hps* can be either a micro presentation space or a normal presentation space (see "GpiCreatePS" in the *Graphics Programming Interface Programming Reference*).

WinDrawText - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_FLAG (0x1019)

An invalid bit was set for a parameter. Use constants defined by PM for options, and do not set any reserved bits.

WinDrawText - Example Code

This example shows how the WinDrawText function can be used to wrap text within a window by using the DT_WORDBREAK flag. The *cchDrawn* variable receives the number of characters actually drawn by the WinDrawText function. If this value is zero, no text is drawn and the for loop is exited. This can occur if the vertical height of the window is too short for the entire text. Otherwise, *cchDrawn* is added to the *hTotalDrawn* variable to provide an offset into the string for the next call to WinDrawText.

```
#define INCL_WINWINDOWMGR          /* Window Manager Functions */
#include <os2.h>

HWND    hwnd;                    /* parent window */

BOOL    rc;      /* Success indicator. */

rc = WinEnableControl(hwndDlg, usId, fEnable);
```

WinEnableControl Parameter - hwndDlg

hwndDlg (**HWND**) - input
Dialog window handle.

WinEnableControl Parameter - usId

usId (**USHORT**) - input
Identity of the item in the dialog template (button id).

WinEnableControl Parameter - fEnable

fEnable (**BOOL**) - input
Enable flag.

WinEnableControl Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinEnableControl - Parameters

hwndDlg (**HWND**) - input
Dialog window handle.

usId (**USHORT**) - input
Identity of the item in the dialog template (button id).

fEnable (**BOOL**) - input
Enable flag.

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinEnableControl - Remarks

This macro expands to:

```
#define WinEnableControl(hwndDlg, usId, fEnable)
WinEnableWindow(WinWindowFromId(hwndDlg, usId), fEnable)
```

This function requires the existence of a message queue.

WinEnableMenuItem

WinEnableMenuItem - Syntax

This macro sets the state of the specified menu item to the enable flag.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND     hwndMenu; /* Menu window handle. */
USHORT   usId;     /* Item identifier. */
BOOL     fEnable;  /* Enable flag. */
BOOL     rc;       /* Success indicator. */

rc = WinEnableMenuItem(hwndMenu, usId, fEnable);
```

WinEnableMenuItem Parameter - hwndMenu

hwndMenu (**HWND**) - input
Menu window handle.

WinEnableMenuItem Parameter - usId

usId (**USHORT**) - input
Item identifier.

WinEnableMenuItem Parameter - fEnable

fEnable (**BOOL**) - input
Enable flag.

WinEnableMenuItem Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinEnableMenuItem - Parameters

hwndMenu ([HWND](#)) - input
Menu window handle.

usId ([USHORT](#)) - input
Item identifier.

fEnable ([BOOL](#)) - input
Enable flag.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinEnableMenuItem - Remarks

This macro expands to:

```
#define WinEnableMenuItem(hwndMenu, usId, fEnable)
((BOOL)WinSendMsg(hwndMenu,
    MM_SETITEMATTR,
    MPFROM2SHORT(usId, TRUE),
    MPFROM2SHORT(MIA_DISABLED, (BOOL)(fEnable) ? 0 : MIA_DISABLED)))
```

This function requires the existence of a message queue.

WinEnablePhysInput

WinEnablePhysInput - Syntax

This function enables or disables queuing of physical input (keyboard or mouse).

```
#define INCL_WININPUT /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwndDesktop; /* Desktop-window handle. */
```

```

BOOL    fEnable;        /* New state for the queuing of physical input. */
BOOL    rc;              /* Previous state for the queuing of physical input. */

rc = WinEnablePhysInput(hwndDesktop, fEnable);

```

WinEnablePhysInput Parameter - hwndDesktop

hwndDesktop ([HWND](#)) - input
Desktop-window handle.

HWND_DESKTOP	The desktop-window handle
Other	Specified desktop-window handle.

WinEnablePhysInput Parameter - fEnable

fEnable ([BOOL](#)) - input
New state for the queuing of physical input.

TRUE	Pointing device and keyboard input are queued
FALSE	Pointing device and keyboard input are disabled.

WinEnablePhysInput Return Value - rc

rc ([BOOL](#)) - returns
Previous state for the queuing of physical input.

TRUE	Pointing device and keyboard input were queued
FALSE	Pointing device and keyboard input were disabled.

WinEnablePhysInput - Parameters

hwndDesktop ([HWND](#)) - input
Desktop-window handle.

HWND_DESKTOP	The desktop-window handle
Other	

Specified desktop-window handle.

fEnable ([BOOL](#)) - input

New state for the queuing of physical input.

TRUE

Pointing device and keyboard input are queued

FALSE

Pointing device and keyboard input are disabled.

rc ([BOOL](#)) - returns

Previous state for the queuing of physical input.

TRUE

Pointing device and keyboard input were queued

FALSE

Pointing device and keyboard input were disabled.

WinEnablePhysInput - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)

An invalid window handle was specified.

WinEnableWindow

WinEnableWindow - Syntax

This function sets the window enabled state.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwnd;          /* Window handle. */
BOOL    fNewEnabled;    /* New enabled state. */
BOOL    rc;             /* Window enabled indicator. */

rc = WinEnableWindow(hwnd, fNewEnabled);
```

WinEnableWindow Parameter - hwnd

hwnd ([HWND](#)) - input
Window handle.

WinEnableWindow Parameter - fNewEnabled

fNewEnabled ([BOOL](#)) - input
New enabled state.

TRUE	Set window state to enabled
FALSE	Set window state to disabled.

WinEnableWindow Return Value - rc

rc ([BOOL](#)) - returns

Window enabled indicator.

TRUE

Window enabled state successfully updated

FALSE

Window enabled state not successfully updated.

WinEnableWindow - Parameters

hwnd ([HWND](#)) - input

Window handle.

fNewEnabled ([BOOL](#)) - input

New enabled state.

TRUE

Set window state to enabled

FALSE

Set window state to disabled.

rc ([BOOL](#)) - returns

Window enabled indicator.

TRUE

Window enabled state successfully updated

FALSE

Window enabled state not successfully updated.

WinEnableWindow - Remarks

If the enable state of *hwnd* is changing, a [WM_ENABLE](#) message is sent before this function returns.

If a window is disabled, its child windows are also disabled, although they are not sent the [WM_ENABLE](#) message. Typically, a window changes appearance when disabled. For example, a disabled push button is displayed with half-tone text.

If *hwnd* is disabled, and it, or one of its descendants, is the focus window, that window loses the focus, so that no window has the focus. However, a disabled window may subsequently be assigned the focus, in which case it should respond to keyboard input.

WinEnableWindow - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)

An invalid window handle was specified.

WinEnableWindow - Example Code

This example uses `WinEnableWindow` to enable the system menu window for the given parent window, after verifying that the parent window handle is valid (`WinIsWindow`), belongs to the calling thread (`WinIsThreadActive`), and is not presently enabled (`WinIsWindowEnabled`).

```
#define INCL_WINWINDOWMGR          /* Window Manager Functions */
#define INCL_WINFRAMEMGR          /* Window Frame Functions */
#include <os2.h>

HAB    hab;           /* anchor-block handle */
HWND    hwndSystemMenu; /* system menu window */
HWND    hwnd;         /* parent window */
BOOL    fSuccess;     /* success indicator */

/* if handle specifies a valid window and the window belongs to the
   current thread, query the enabled status of the system menu */
if (WinIsWindow(hab, hwnd) && WinIsThreadActive(hab))
{
    /* obtain handle for system menu */
    hwndSystemMenu = WinWindowFromID(hwnd, FID_SYSMENU);

    /* if system menu is not enabled, enable it */
    if (!WinIsWindowEnabled(hwndSystemMenu))
        fSuccess = WinEnableWindow(hwndSystemMenu, TRUE);
}

WinEnableWindowUpdate

WinEnableWindowUpdate - Syntax

This function sets the window visibility state for subsequent drawing.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */  
#include <os2.h>
```

```
HWND    hwnd;        /* Window handle. */  
BOOL    fEnable;     /* New visibility state. */  
BOOL    rc;          /* Visibility-changed indicator. */
```

```
rc = WinEnableWindowUpdate(hwnd, fEnable);
```

WinEnableWindowUpdate Parameter - hwnd

hwnd (**HWND**) - input
Window handle.

WinEnableWindowUpdate Parameter - fEnable

fEnable (**BOOL**) - input
New visibility state.

TRUE

FALSE	Set window state visible
	Set window state invisible.

WinEnableWindowUpdate Return Value - rc

rc ([BOOL](#)) - returns
Visibility-changed indicator.

TRUE	Window visibility successfully changed
FALSE	Window visibility not successfully changed.

WinEnableWindowUpdate - Parameters

hwnd ([HWND](#)) - input
Window handle.

fEnable ([BOOL](#)) - input
New visibility state.

TRUE	Set window state visible
FALSE	Set window state invisible.

rc ([BOOL](#)) - returns
Visibility-changed indicator.

TRUE	Window visibility successfully changed
FALSE	Window visibility not successfully changed.

WinEnableWindowUpdate - Remarks

This function can be used to defer drawing when making a series of changes to a window. A window can be redrawn by using the [WinShowWindow](#) function.

WS_VISIBLE (style bit of a window) is set to *fEnable* without causing redrawing. That is, if the window was previously visible, it remains visible on the device when WS_VISIBLE is set to 0, and if the window was previously invisible, it is not shown when WS_VISIBLE is set to 1. If *fEnable* is set to TRUE, any subsequent drawing into the window is visible. If *fEnable* is set to FALSE, any subsequent drawing into the window is not visible.

If the value of the WS_VISIBLE style bit has been changed, the [WM_SHOW](#) message is sent to the window of *hwnd* before the call returns.

Any alteration to the appearance of a window disabled for window update is not presented. Therefore, the application must ensure that the window is redrawn. To show a window and ensure that it is redrawn after calling the WinEnableWindowUpdate function with *fEnable* set to FALSE, use the [WinShowWindow](#) function with *fNewVisibility* set to TRUE. In particular, if a window is destroyed while in this state its image is not removed from the display. After window updating is reenabled, the application should ensure that the window gets totally invalidated so that it repaints.

WinEnableWindowUpdate - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

PMERR_INVALID_FLAG (0x1019)
An invalid bit was set for a parameter. Use constants defined by PM for options, and do not set any reserved bits.

WinEndEnumWindows

WinEndEnumWindows - Syntax

This function ends the enumeration process for a specified enumeration.

```

#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HENUM    henum; /* Enumeration handle. */
BOOL     rc;    /* Success indicator. */

rc = WinEndEnumWindows(henum);

```

WinEndEnumWindows Parameter - henum

henum (**HENUM**) - input
Enumeration handle.

Returned by previous call to the [WinBeginEnumWindows](#) call.

WinEndEnumWindows Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinEndEnumWindows - Parameters

henum ([HENUM](#)) - input
Enumeration handle.

Returned by previous call to the [WinBeginEnumWindows](#) call.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinEndEnumWindows - Remarks

This function destroys the window hierarchy remembered by the [WinBeginEnumWindows](#) function. After this function, the *henum* parameter is no longer valid.

WinEndEnumWindows - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HENUM (0x101C)
An invalid enumeration handle was specified.

WinEndPaint

WinEndPaint - Syntax

This function indicates that the redrawing of a window is complete, generally as part of the processing of a [WM_PAINT](#) message.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HPS    hps; /* Presentation-space handle. */
BOOL    rc; /* Success indicator. */

rc = WinEndPaint(hps);
```

WinEndPaint Parameter - hps

hps ([HPS](#)) - input
Presentation-space handle.

Handle of the presentation space that is used for drawing and that is returned by a previous call to the [WinBeginPaint](#) function.

WinEndPaint Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinEndPaint - Parameters

hps ([HPS](#)) - input
Presentation-space handle.

Handle of the presentation space that is used for drawing and that is returned by a previous call to the [WinBeginPaint](#) function.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinEndPaint - Remarks

The presentation space is restored to its state before the [WinBeginPaint](#) function:

- Cache presentation space is returned to the cache.
- Other presentation spaces have their original drawing state restored, including reassociating the original device context (if there was one).

If the pointer is hidden by the [WinBeginPaint](#) function, it is reshown by this function.

Any child windows having a synchronous painting style of the window associated with the presentation space are updated during the processing of this function, if they have non-NULL update regions.

WinEnumClipbrdFmts

WinEnumClipbrdFmts - Syntax

This function enumerates the list of clipboard data formats available in the clipboard.

```

#define INCL_WINCLIPBOARD /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB    hab;          /* Anchor-block handle. */
ULONG   fmt;          /* Previous clipboard-data format index. */
ULONG   ulNext;       /* Next clipboard-data format index. */

ulNext = WinEnumClipbrdFmts(hab, fmt);

```

WinEnumClipbrdFmts Parameter - hab

hab ([HAB](#)) - input

Anchor-block handle.

WinEnumClipbrdFmts Parameter - fmt

fmt ([ULONG](#)) - input

Previous clipboard-data format index.

Specifies the index of the last clipboard data format enumerated using this function.

This should start at zero, in which instance the first available format is obtained. Subsequently, it should be set to the last format index value returned by this function.

WinEnumClipbrdFmts Return Value - ulNext

ulNext ([ULONG](#)) - returns

Next clipboard-data format index.

Possible values include:

- | | |
|-------|--|
| 0 | Enumeration is complete; that is, there are no more clipboard formats available. |
| Other | Index of the next available clipboard-data format in the clipboard. |
-

WinEnumClipbrdFmts - Parameters

hab ([HAB](#)) - input

Anchor-block handle.

fmt ([ULONG](#)) - input

Previous clipboard-data format index.

Specifies the index of the last clipboard data format enumerated using this function.

This should start at zero, in which instance the first available format is obtained. Subsequently, it should be set to the last format index value returned by this function.

ulNext ([ULONG](#)) - returns

Next clipboard-data format index.

Possible values include:

- | | |
|-------|--|
| 0 | Enumeration is complete; that is, there are no more clipboard formats available. |
| Other | Index of the next available clipboard-data format in the clipboard. |
-

WinEnumClipbrdFmts - Remarks

The clipboard should be open before this function is used.

WinEnumDlgItem

WinEnumDlgItem - Syntax

This function returns the window handle of a dialog item within a dialog window.

```
#define INCL_WINDIALOGS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND     hwndDlg;    /* Dialog-window handle. */
HWND     hwnd;       /* Child-window handle. */
ULONG    code;       /* Item-type code. */
HWND     hwndItem;   /* Item-window handle. */

hwndItem = WinEnumDlgItem(hwndDlg, hwnd, code);
```

WinEnumDlgItem Parameter - hwndDlg

hwndDlg (**HWND**) - input
Dialog-window handle.

WinEnumDlgItem Parameter - hwnd

hwnd (**HWND**) - input
Child-window handle.

This may be an immediate child of the dialog window or a window lower in the window hierarchy, such as a child of a child window.

NULLHANDLE can be specified if *code* is EDI_FIRSTTABITEM or EDI_LASTTABITEM.

If an invalid handle is passed, the first child window of the dialog is returned.

WinEnumDlgItem Parameter - code

code (**ULONG**) - input
Item-type code.

Determines the type of dialog item to return. This parameter can have one of the following values:

EDI_FIRSTGROUPITEM
First item in the same group.

EDI_FIRSTTABITEM
First item in dialog with style **WS_TABSTOP**. *hwnd* is ignored.

EDI_LASTGROUPITEM
Last item in the same group.

EDI_LASTTABITEM
Last item in dialog with style **WS_TABSTOP**. *hwnd* is ignored.

EDI_NEXTGROUPITEM
Next item in the same group. Wraps around to beginning of group when the end of the group is reached.

EDI_NEXTTABITEM
Next item with style **WS_TABSTOP**. Wraps around to beginning of dialog item list when end is reached.

EDI_PREVGROUPITEM
Previous item in the same group. Wraps around to end of group when the start of the group is reached. For information on the **WS_GROUP** style,

EDI_PREVTABITEM
Previous item with style **WS_TABSTOP**. Wraps around to end of dialog item list when beginning is reached.

WinEnumDlgItem Return Value - hwndItem

hwndItem (**HWND**) - returns
Item-window handle.

As dictated by *code*.

The window is always an immediate child of *hwndDlg*, even if *hwnd* is not an immediate child window.

WinEnumDlgItem - Parameters

hwndDlg (**HWND**) - input
Dialog-window handle.

hwnd (**HWND**) - input
Child-window handle.

This may be an immediate child of the dialog window or a window lower in the window hierarchy, such as a child of a child window.

NULLHANDLE can be specified if *code* is **EDI_FIRSTTABITEM** or **EDI_LASTTABITEM**.

If an invalid handle is passed, the first child window of the dialog is returned.

code (**ULONG**) - input
Item-type code.

Determines the type of dialog item to return. This parameter can have one of the following values:

EDI_FIRSTGROUPITEM

First item in the same group.

EDI_FIRSTTABITEM

First item in dialog with style WS_TABSTOP. *hwnd* is ignored.

EDI_LASTGROUPITEM

Last item in the same group.

EDI_LASTTABITEM

Last item in dialog with style WS_TABSTOP. *hwnd* is ignored.

EDI_NEXTGROUPITEM

Next item in the same group. Wraps around to beginning of group when the end of the group is reached.

EDI_NEXTTABITEM

Next item with style WS_TABSTOP. Wraps around to beginning of dialog item list when end is reached.

EDI_PREVGROUPITEM

Previous item in the same group. Wraps around to end of group when the start of the group is reached. For information on the WS_GROUP style,

EDI_PREVTABITEM

Previous item with style WS_TABSTOP. Wraps around to end of dialog item list when beginning is reached.

hwndItem ([HWND](#)) - returns
Item-window handle.

As dictated by *code*.

The window is always an immediate child of *hwndDlg*, even if *hwnd* is not an immediate child window.

WinEnumDlgItem - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinEnumDlgItem - Example Code

This example uses WinEnumDlgItem to query the first dialog item for each immediate child of the specified dialog window. The immediate children are enumerated using a WinBeginEnumWindows - WinGetNextWindow - WinEndEnumWindows loop.

```
#define INCL_WINDIALOGS      /* Window Dialog Mgr functions */
#define INCL_WINWINDOWMGR   /* Window Manager functions */
#include <os2.h>

HWND  hwndDlg;           /* Handle of the parent dialog window */
HWND  hwndChild;         /* Current dialog child */
HWND  hwndItem;          /* First dialog item */
HENUM henum;             /* Enumeration handle */
BOOL  fSuccess;          /* Success indicator */

henum = WinBeginEnumWindows(hwndDlg);
while ((hwndChild = WinGetNextWindow(henum)) != NULL)
    hwndItem = WinEnumDlgItem(hwndDlg, hwndChild, EDI_FIRSTTABITEM);
fSuccess = WinEndEnumWindows(henum);
```

WinEnumObjectClasses

WinEnumObjectClasses - Syntax

The WinEnumObjectClasses function will return a list of all workplace object classes that have been registered.

```
#define INCL_WINWORKPLACE
#include <os2.h>

POBJCLASS  pObjClass; /* Pointer to object class. */
PULONG     pSize;     /* Length of the pObjClass buffer in bytes. */
BOOL       rc;        /* Success indicator. */

rc = WinEnumObjectClasses(pObjClass, pSize);
```

WinEnumObjectClasses Parameter - pObjClass

pObjClass ([POBJCLASS](#)) - input
Pointer to object class.

A pointer to a buffer to be filled with information about the registered workplace object classes.

WinEnumObjectClasses Parameter - pSize

pSize ([PULONG](#)) - in/out
Length of the *pObjClass* buffer in bytes.

If *pObjClass* is NULL, the actual size of *pObjClass* is returned in *pSize*

WinEnumObjectClasses Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinEnumObjectClasses - Parameters

pObjClass ([POBJCLASS](#)) - input
Pointer to object class.

A pointer to a buffer to be filled with information about the registered workplace object classes.

pSize ([PULONG](#)) - in/out
Length of the *pObjClass* buffer in bytes.

If *pObjClass* is NULL, the actual size of *pObjClass* is returned in *pSize*

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinEnumObjectClasses - Remarks

WinEnumObjectClasses will return a buffer containing all workplace object classes that are currently registered with the system. Workplace object classes are registered with the system through the function call [WinRegisterObjectClass](#).

WinEqualRect

WinEqualRect - Syntax

This function compares two rectangles for equality.

```
#define INCL_WINRECTANGLES /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;      /* Anchor-block handle. */
PRECTL   prcl1;    /* First rectangle. */
PRECTL   prcl2;    /* Second rectangle. */
BOOL      rc;       /* Equality indicator. */

rc = WinEqualRect(hab, prcl1, prcl2);
```

WinEqualRect Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinEqualRect Parameter - prcl1

prcl1 ([PRECTL](#)) - input
First rectangle.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) can also be used, if supported by the language.

WinEqualRect Parameter - prcl2

prcl2 ([PRECTL](#)) - input
Second rectangle.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) can also be used, if supported by the language.

WinEqualRect Return Value - rc

rc ([BOOL](#)) - returns
Equality indicator.

TRUE	Rectangles are identical
FALSE	Rectangles are not identical, or an error occurred.

WinEqualRect - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

prcl1 ([PRECTL](#)) - input
First rectangle.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) can also be used, if supported by the language.

prcl2 ([PRECTL](#)) - input

Second rectangle.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) can also be used, if supported by the language.

rc ([BOOL](#)) - returns
Equality indicator.

TRUE

Rectangles are identical

FALSE

Rectangles are not identical, or an error occurred.

WinEqualRect - Remarks

If both rectangles are empty (for example, they are considered equal even if the actual coordinate values are different).

WinEqualRect - Related Functions

WinExcludeUpdateRegion

WinExcludeUpdateRegion - Syntax

This function subtracts the update region (invalid region) of a window from the clipping region of a presentation space.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HPS      hps;           /* Presentation-space handle whose clipping region is to be updated. */
HWND     hwnd;          /* Window handle. */
LONG     lComplexity;    /* Complexity value. */

lComplexity = WinExcludeUpdateRegion(hps,
                                     hwnd);
```

WinExcludeUpdateRegion Parameter - hps

hps ([HPS](#)) - input

Presentation-space handle whose clipping region is to be updated.

WinExcludeUpdateRegion Parameter - hwnd

hwnd ([HWND](#)) - input

Window handle.

Handle of window whose update region is subtracted from the clipping region of the presentation space.

WinExcludeUpdateRegion Return Value - lComplexity

lComplexity ([LONG](#)) - returns
Complexity value.

This indicates the resulting form of the clipping area. The values and meanings of this parameter are defined in `GpiCombineRegion`.

Complexity of resulting region/error indicator:

<code>RGN_NULL</code>	Null Region
<code>RGN_RECT</code>	Rectangle region
<code>RGN_COMPLEX</code>	Complex region
<code>RGN_ERROR</code>	Error.

WinExcludeUpdateRegion - Parameters

hps ([HPS](#)) - input
Presentation-space handle whose clipping region is to be updated.

hwnd ([HWND](#)) - input
Window handle.

Handle of window whose update region is subtracted from the clipping region of the presentation space.

lComplexity ([LONG](#)) - returns
Complexity value.

This indicates the resulting form of the clipping area. The values and meanings of this parameter are defined in `GpiCombineRegion`.

Complexity of resulting region/error indicator:

<code>RGN_NULL</code>	Null Region
<code>RGN_RECT</code>	Rectangle region
<code>RGN_COMPLEX</code>	Complex region
<code>RGN_ERROR</code>	Error.

WinExcludeUpdateRegion - Remarks

This function is typically used to prevent drawing into parts of a window that are known to be invalid, as during an incremental update optimization process.

It is the application's responsibility to reset the clipping region when necessary.

WinExcludeUpdateRegion - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinExcludeUpdateRegion - Example Code

This example uses `WinExcludeUpdateRegion` to prevent drawing into the window's known invalid regions (to optimize updates) by excluding the window's update region from the clipping region of the presentation space. The clipping region will need to be reset later by the application, which can be accomplished using `GpiIntersectClipRectangle` with the rectangle comprising the window as input.

```
#define INCL_WINWINDOWMGR      /* Window Manager Functions */
#define INCL_GPIREGIONS      /* Region functions */
#include <os2.h>

LONG lComplexity;      /* clipping complexity/error return */
HWND hwnd;            /* parent window */
RECT rcl;              /* update region */
HPS hps;              /* presentation-space handle */

case WM_PAINT:
    lComplexity = WinExcludeUpdateRegion(hps, hwnd);

    hps = WinBeginPaint(hwnd, /* handle of the window */
        NULLHANDLE,          /* get a cache presentation space */
        &rcl);                /* receives update rectangle */
    WinFillRect(hps, &rcl, CLR_WHITE);
    WinEndPaint(hps);
```

WinFileDlg

WinFileDlg - Syntax

This function creates and displays the file dialog and returns the user's selection or selections.

```
#define INCL_winstdfile
#include <os2.h>

HWND      hwndP;      /* Parent-window handle. */
HWND      hwndO;      /* Requested owner-window handle. */
PFILEDLG  pfild;      /* Pointer to a FILEDLG structure. */
HWND      hwndDlg;    /* File dialog window handle. */

hwndDlg = WinFileDlg(hwndP, hwndO, pfild);
```

WinFileDlg Parameter - hwndP

hwndP ([HWND](#)) - input

Parent-window handle.

Parent-window handle of the created dialog window.

HWND_DESKTOP

The desktop window.

Other

Specified window.

WinFileDlg Parameter - hwndO

hwndO ([HWND](#)) - input

Requested owner-window handle.

Requested owner-window handle of the created dialog window.

The actual owner window is calculated using the algorithm specified in the description of the [WinLoadDlg](#) function.

WinFileDlg Parameter - pfiled

pfiled ([PFILEDLG](#)) - input
Pointer to a [FILEDLG](#) structure.

WinFileDlg Return Value - hwndDlg

hwndDlg ([HWND](#)) - returns
File dialog window handle.

If the flag is set by the application, the return value is the window handle of the file dialog, or NULLHANDLE if the dialog cannot be created. If the flag is not set, the return value is TRUE if dialog creation is successful, or NULLHANDLE if it is unsuccessful.

WinFileDlg - Parameters

hwndP ([HWND](#)) - input
Parent-window handle.

Parent-window handle of the created dialog window.

HWND_DESKTOP
The desktop window.

Other
Specified window.

hwndO ([HWND](#)) - input
Requested owner-window handle.

Requested owner-window handle of the created dialog window.

The actual owner window is calculated using the algorithm specified in the description of the [WinLoadDlg](#) function.

pfiled ([PFILEDLG](#)) - input
Pointer to a [FILEDLG](#) structure.

hwndDlg ([HWND](#)) - returns
File dialog window handle.

If the flag is set by the application, the return value is the window handle of the file dialog, or NULLHANDLE if the dialog cannot be created. If the flag is not set, the return value is TRUE if dialog creation is successful, or NULLHANDLE if it is unsuccessful.

WinFileDlg - Remarks

The *pfild* parameter is required and the [FILEDLG](#) structure must be properly initialized.

On return, the [FILEDLG](#) structure is updated with any user alterations, and the field is set to the value returned by the file dialog's [WinDismissDlg](#) function. By default, this is the ID of the push button pressed to dismiss the dialog, DID_OK or DID_CANCEL, unless the application supplied additional push buttons in its template.

For convenience, the pointer to the [FILEDLG](#) structure is placed in the QWL_USER field of the dialog's frame window. If in a custom file dialog procedure the pointer to the [FILEDLG](#) structure is desired, it should be queried from the frame window with the [WinQueryWindowULong](#) function.

To subclass the default file dialog with a new template, the application must give the module and ID of the new file dialog template and the address of a dialog procedure for message handling. Window IDs in the range 0x0000 through 0x0FFF are reserved for the standard file dialog controls. IDs from outside this range must be chosen for any controls or windows added to a custom file dialog.

When a modeless dialog is dismissed, the owner of the file dialog will receive a [WM_COMMAND](#) message with the the ID of the file dialog.

WinFileDlg - Example Code

This example uses WinFileDlg to create and display a single file selection dialog using the system default open file dialog template and procedure.

```
#define INCL_WINSTDFILE          /* Window Standard File      */
                                /* functions                    */
#include <os2.h>

FILEDLG fild;                  /* File dialog info structure */
char pszTitle[10] = "Open File"; /* Title of dialog           */
char pszFullFile[CCHMAXPATH] = "*.C"; /* File filter string        */
HWND hwndMain;                 /* Window that owns the file */
                                /* dialog                     */
HWND hwndDlg;                  /* File dialog window        */

/* Initially set all fields to 0 */
memset(&pfidFiledlg, 0, sizeof(FILEDLG));

/* Initialize those fields in the FILEDLG structure */
/* that are used by the application */
fild.cbSize = sizeof(FILEDLG); /* Size of structure         */
fild.fl = FDS_HELPBUTTON |    /* FDS_* flags               */
         FDS_CENTER |
         FDS_OPEN_DIALOG;
fild.pszTitle = pszTitle;      /* Dialog title string       */

/* Initial path, file name, or file filter */
strcpy(fild.szFullFile, pszFullFile);

/* Display the dialog and get the file */
hwndDlg = WinFileDlg(HWND_DESKTOP, hwndMain, &fild);
if (hwndDlg && (pfild.lReturn == DID_OK))
{
    /* Upon successful return of a file, open it for reading */
    /* and further processing */
}
```

WinFileDlg - Topics

Select an item:

[Syntax](#)

[Parameters](#)

[Returns](#)

WinFillRect

WinFillRect - Syntax

This function draws a filled rectangular area.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HPS      hps;      /* Presentation-space handle. */
PRECTL   prcl;     /* Rectangle to be filled, in window coordinates. */
LONG     lColor;    /* Color with which to fill the rectangle. */
BOOL     rc;        /* Success indicator. */

rc = WinFillRect(hps, prcl, lColor);
```

WinFillRect Parameter - hps

hps ([HPS](#)) - input
Presentation-space handle.

This can be either a micro-presentation space or a normal presentation space.

WinFillRect Parameter - prcl

prcl ([PRECTL](#)) - input
Rectangle to be filled, in window coordinates.

Points on the left and bottom boundaries of the rectangle are included in the fill, but points on the right and top boundaries are not, except where they are also on the left and bottom boundaries; that is, the top-left and bottom-right corners.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) can also be used, if supported by the language.

WinFillRect Parameter - lColor

IColor ([LONG](#)) - input
Color with which to fill the rectangle.

This is either a color index, or an RGB color value, depending upon whether and how a logical color table has been loaded. (See "GdiCreateLogColorTable" in the *Graphics Programming Interface Programming Reference*.)

WinFillRect Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinFillRect - Parameters

hps ([HPS](#)) - input
Presentation-space handle.

This can be either a micro-presentation space or a normal presentation space.

prcl ([PRECTL](#)) - input
Rectangle to be filled, in window coordinates.

Points on the left and bottom boundaries of the rectangle are included in the fill, but points on the right and top boundaries are not, except where they are also on the left and bottom boundaries; that is, the top-left and bottom-right corners.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) can also be used, if supported by the language.

IColor ([LONG](#)) - input
Color with which to fill the rectangle.

This is either a color index, or an RGB color value, depending upon whether and how a logical color table has been loaded. (See "GdiCreateLogColorTable" in the *Graphics Programming Interface Programming Reference*.)

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinFillRect - Remarks

This function does not change any presentation space state.

This function must only be used in draw mode (DM_DRAW) to a screen device context.

If an empty rectangle is specified, this function draws nothing and completes successfully (that is, TRUE is returned).

WinFindAtom

WinFindAtom - Syntax

This function finds an atom in the atom table.

```
#define INCL_WINATOM /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HATOMTBL    hatomtblAtomTbl; /* Atom-table handle. */
PSZ         pszAtomName;     /* Atom name. */
ATOM        atom;             /* Atom value. */

atom = WinFindAtom(hatomtblAtomTbl, pszAtomName);
```

WinFindAtom Parameter - hatomtblAtomTbl

hatomtblAtomTbl ([HATOMTBL](#)) - input
Atom-table handle.

This is the handle returned from a previous [WinCreateAtomTable](#) or [WinQuerySystemAtomTable](#) function.

WinFindAtom Parameter - pszAtomName

pszAtomName ([PSZ](#)) - input
Atom name.

This is a null terminated character string to be found in the table.

If the string begins with a "#" character, the five ASCII digits that follow are converted into an integer atom.

If the string begins with a "!" character, the next two bytes are interpreted as an atom.

If the high order word of the string is -1, the low order word is an atom.

WinFindAtom Return Value - atom

atom ([ATOM](#)) - returns
Atom value.

Atom	The atom associated with the passed string
0	Invalid atom table handle or invalid atom name specified.

WinFindAtom - Parameters

hatomtblAtomTbl ([HATOMTBL](#)) - input
Atom-table handle.

This is the handle returned from a previous [WinCreateAtomTable](#) or [WinQuerySystemAtomTable](#) function.

pszAtomName ([PSZ](#)) - input
Atom name.

This is a null terminated character string to be found in the table.

If the string begins with a "#" character, the five ASCII digits that follow are converted into an integer atom.

If the string begins with a "!" character, the next two bytes are interpreted as an atom.

If the high order word of the string is -1, the low order word is an atom.

atom ([ATOM](#)) - returns
Atom value.

Atom	The atom associated with the passed string
0	Invalid atom table handle or invalid atom name specified.

WinFindAtom - Remarks

This function is identical to the [WinAddAtom](#) function, except that:

- If the atom name is not found in the table, it is not added to the table and 0 is returned.
- If the atom name is found in the table, the use count is not incremented.

Because integer atoms do not have a use count and do not actually occupy memory in the atom table, this function is identical to [WinAddAtom](#) with respect to integer atoms.

WinFindAtom - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HATOMTBL (0x1013)
An invalid atom-table handle was specified.

PMERR_INVALID_INTEGER_ATOM (0x1016)
The specified atom is not a valid integer atom.

PMERR_INVALID_ATOM_NAME (0x1015)
An invalid atom name string was passed.

PMERR_ATOM_NAME_NOT_FOUND (0x1017)
The specified atom name is not in the atom table.

WinFlashWindow

WinFlashWindow - Syntax

This function starts or stops a window flashing.

```
#define INCL_WINFRAMEMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwndFrame; /* Handle of window to be flashed. */
BOOL    fFlash;    /* Start-flashing indicator. */
BOOL    rc;         /* Success indicator. */

rc = WinFlashWindow(hwndFrame, fFlash);
```

WinFlashWindow Parameter - hwndFrame

hwndFrame ([HWND](#)) - input
Handle of window to be flashed.

WinFlashWindow Parameter - fFlash

fFlash ([BOOL](#)) - input
Start-flashing indicator.

TRUE	Start window flashing
FALSE	Stop window flashing.

WinFlashWindow Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinFlashWindow - Parameters

hwndFrame ([HWND](#)) - input
Handle of window to be flashed.

fFlash ([BOOL](#)) - input
Start-flashing indicator.

TRUE	Start window flashing
FALSE	Stop window flashing.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinFlashWindow - Remarks

Flashing a window brings the user's attention to a window that is not the active window, where some important message or dialog must be seen by the user.

Flashing is typically done by inverting the title bar continuously. The alarm is sounded for the first five flashes.

Note: It should be used only for important messages, for example, where some component of the system is failing and requires immediate attention to avoid damage.

WinFlashWindow - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)

An invalid window handle was specified.

WinFlashWindow - Example Code

This example uses WinFlashWindow to flash an inactive window to draw the user's attention to an important message in the window.

```
#define INCL_WINFRAMEMGR      /* Window Frame Functions */
#define INCL_WINDIALOGS      /* Window Dialog Mgr Functions */
#include <os2.h>

BOOL fSuccess;               /* Success indicator */
HWND hwnd;                  /* window handle */

/* flash window to get user's attention */
fSuccess = WinFlashWindow(hwnd, TRUE);

/* vital message is displayed */
WinMessageBox(HWND_DESKTOP,
    hwnd,                  /* client-window handle */
    "Important message: must be seen by user", /* message */
    "Vital message",       /* title of the message */
    0,                     /* message box id */
    MB_NOICON | MB_OK);    /* icon and button flags */
```

WinFocusChange

WinFocusChange - Syntax

This function changes the focus window.

```
#define INCL_WININPUT /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HWND     hwndDesktop;    /* Desktop-window handle. */
HWND     hwndNewFocus;   /* Window handle to receive the focus. */
ULONG    flFocusChange;  /* Focus changing indicators. */
BOOL     rc;             /* Success indicator. */

rc = WinFocusChange(hwndDesktop, hwndNewFocus,
                    flFocusChange);
```

WinFocusChange Parameter - hwndDesktop

hwndDesktop ([HWND](#)) - input
Desktop-window handle.

HWND_DESKTOP	The desktop-window handle
Other	Specified desktop-window handle.

WinFocusChange Parameter - hwndNewFocus

hwndNewFocus ([HWND](#)) - input
Window handle to receive the focus.

WinFocusChange Parameter - flFocusChange

flFocusChange ([ULONG](#)) - input
Focus changing indicators.

These indicators are passed on in the [WM_FOCUSCHANGE](#) message:

FC_NOSETFOCUS	Do not send the WM_SETFOCUS message to the window receiving the focus.
---------------	--

FC_NOLOSEFOCUS	Do not send the WM_SETFOCUS message to the window losing the focus.
----------------	---

FC_NOSETACTIVE	
----------------	--

Do not send the [WM_ACTIVATE](#) message to the window being activated.

FC_NOLOSEACTIVE

Do not send the [WM_ACTIVATE](#) message to the window being deactivated.

FC_NOSETSELECTION

Do not send the [WM_SETSELECTION](#) message to the window being selected.

FC_NOLOSESELECTION

Do not send the [WM_SETSELECTION](#) message to the window being deselected.

FC_NOBRINGTOTOP

Do not bring any window to the top.

FC_NOBRINGTOTOPFIRSTWINDOW

Do not bring the first frame window to the top.

WinFocusChange Return Value - rc

rc ([BOOL](#)) - returns

Success indicator.

TRUE

Successful completion

FALSE

Error occurred.

WinFocusChange - Parameters

hwndDeskTop ([HWND](#)) - input

Desktop-window handle.

HWND_DESKTOP

The desktop-window handle

Other

Specified desktop-window handle.

hwndNewFocus ([HWND](#)) - input

Window handle to receive the focus.

flFocusChange ([ULONG](#)) - input

Focus changing indicators.

These indicators are passed on in the [WM_FOCUSCHANGE](#) message:

FC_NOSETFOCUS

Do not send the [WM_SETFOCUS](#) message to the window receiving the focus.

FC_NOLOSEFOCUS

Do not send the [WM_SETFOCUS](#) message to the window losing the focus.

FC_NOSETACTIVE

Do not send the [WM_ACTIVATE](#) message to the window being activated.

FC_NOLOSEACTIVE

Do not send the [WM_ACTIVATE](#) message to the window being deactivated.

FC_NOSETSELECTION

Do not send the [WM_SETSELECTION](#) message to the window being selected.

FC_NOLOSESELECTION

Do not send the [WM_SETSELECTION](#) message to the window being deselected.

FC_NOBRINGTOTOP

Do not bring any window to the top.

FC_NOBRINGTOTOPFIRSTWINDOW

Do not bring the first frame window to the top.

rc ([BOOL](#)) - returns
Success indicator.

TRUE

Successful completion

FALSE

Error occurred.

WinFocusChange - Remarks

This function sends a [WM_FOCUSCHANGE](#) message to the window that is losing the focus and a [WM_FOCUSCHANGE](#) message to the window that is receiving the focus.

This function fails if another process or thread is currently using this function.

Other messages may be sent as a consequence of the frame control processing of the [WM_FOCUSCHANGE](#) (in [Frame Controls](#)) message, depending on the value of the *//FocusChange* parameter. These messages, if sent, are sent in this order:

1. [WM_SETFOCUS](#) to the window losing the focus.
2. [WM_SETSELECTION](#) to the windows losing their selection.
3. [WM_ACTIVATE](#) to the windows being deactivated.
4. [WM_ACTIVATE](#) to the windows being activated.
5. [WM_SETSELECTION](#) to the windows being selected.
6. [WM_SETFOCUS](#) to the window receiving the focus.

Note: If the [WinQueryFocus](#) function is used during processing of this function:

- The window handle of the window losing the focus is returned while the [WM_FOCUSCHANGE](#) message with the is being processed.
- The window handle of the window receiving the focus is returned while the [WM_FOCUSCHANGE](#) (in [Frame Controls](#)) message with the is being processed.

If the [WinQueryActiveWindow](#) function is used during processing of this function:

- The window handle of the window being deactivated is returned while the [WM_ACTIVATE](#) message with the is being processed.
- The window handle of the window being activated is returned while the [WM_ACTIVATE](#) message with the is being processed.

Also, there is a short period during the time after the old active window has acted on the deactivation message and before the new active window has acted on the activation message when the [WinQueryActiveWindow](#) function returns `NULLHANDLE`.

This function should not be made unless it is directly or indirectly the result of operator input.

Even if `FC_NOSETSELECTION` is not specified, the [WM_SETSELECTION](#) is not sent to a frame window that is already selected. This can occur if the focus is being transferred from a parent to a child window and `FC_NOLOSESELECTION` was specified.

WinFocusChange - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinFontDlg

WinFontDlg - Syntax

This dialog allows the user to select a font.

```
#define INCL_winstdfont
#include <os2.h>

HWND      hwndP; /* Parent-window handle. */
HWND      hwndO; /* Requested owner-window handle. */
PFONDLG   pfntd; /* Pointer to an initialized FONDLG structure. */
HWND      hwnd;  /* Font dialog window handle. */

hwnd = WinFontDlg(hwndP, hwndO, pfntd);
```

WinFontDlg Parameter - hwndP

hwndP ([HWND](#)) - input

Parent-window handle.

Parent-window handle of the created dialog window.

[HWND_DESKTOP](#)

The desktop window.

Other

Specified window.

WinFontDlg Parameter - hwndO

hwndO ([HWND](#)) - input

Requested owner-window handle.

Requested owner-window handle of the created dialog window.

The actual owner window is calculated using the algorithm specified in the description of the [WinLoadDlg](#) function.

WinFontDlg Parameter - pfntd

pfntd ([PFONTDLG](#)) - input
Pointer to an initialized [FONTDLG](#) structure.

WinFontDlg Return Value - hwnd

hwnd ([HWND](#)) - returns
Font dialog window handle.

If the flag is set by the application, the return value is the window handle of the font dialog, or NULLHANDLE if the dialog cannot be created. If the flag is not set, the return value is TRUE if dialog creation is successful, or NULLHANDLE if it is unsuccessful.

WinFontDlg - Parameters

hwndP ([HWND](#)) - input
Parent-window handle.

Parent-window handle of the created dialog window.

[HWND_DESKTOP](#)
The desktop window.
Other
Specified window.

hwndO ([HWND](#)) - input
Requested owner-window handle.

Requested owner-window handle of the created dialog window.

The actual owner window is calculated using the algorithm specified in the description of the [WinLoadDlg](#) function.

pfntd ([PFONTDLG](#)) - input
Pointer to an initialized [FONTDLG](#) structure.

hwnd ([HWND](#)) - returns
Font dialog window handle.

If the flag is set by the application, the return value is the window handle of the font dialog, or NULLHANDLE if the dialog cannot be created. If the flag is not set, the return value is TRUE if dialog creation is successful, or NULLHANDLE if it is unsuccessful.

WinFontDlg - Remarks

The *pfntd* parameter is required and the [FONTDLG](#) structure must be properly initialized.

Note: If the field in the [FONTDLG](#) structure, *pfntd* must be a pointer to a [FONTDLG](#) structure that is either static or allocated from the heap. This [FONTDLG](#) structure must not be allocated on the stack.

Upon return, the [FONTDLG](#) structure is updated with any user alterations and the field contains the value returned by the font dialog's [WinDismissDlg](#) function. By default this is the ID of the push button pressed to dismiss the dialog, DID_OK or DID_CANCEL, unless the application supplied additional push buttons in its template.

The pointer to the [FONTDLG](#) structure is placed in the QWL_USER field of the dialog's frame window. If in a custom font dialog procedure the pointer to the [FONTDLG](#) structure is desired, it should be queried from the frame window with [WinQueryWindowULong](#).

To subclass the default font dialog with a new template, the application must give the module and ID of the new font dialog template and the address of a dialog procedure for message handling. Window IDs in the range 0x0000 through 0x0FFF are reserved for the font dialog controls. IDs from outside this range must be chosen for any controls added to a custom font dialog.

When a modeless dialog is dismissed, the owner of the font dialog will receive a [WM_COMMAND](#) message with the parameter equal to the ID of the font dialog.

WinFontDlg - Example Code

This example displays a font selection dialog by using WinFontDlg, which allows the user to select a font.

```
#define INCL_WINSTDFONT      /* Window Standard Font Functions */
#include <os2.h>
#include <string.h>

HPS      hpsScreen;          /* Screen presentation space */
FONTDLG  pfdFontdlg;         /* Font dialog info structure */
HWND     hwndMain;          /* Window that owns the font dialog */
HWND     hwndFontDlg;        /* Font dialog window */

char  szFamilyname[FACESIZE];

/*****
/* Initially set all fields to 0.
*****/
memset(&pfdFontdlg,0,sizeof(FONTDLG));

/*****
/* Get handle to presentation space.

WinFreeErrorInfo

WinFreeErrorInfo - Syntax

This function releases memory allocated for an error-information block.

```

#define INCL_WINERRORS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

PERRINFO    perriErrorInfo; /* Error-information block whose memory is to be released. */
BOOL        rc;             /* Success indicator. */

rc = WinFreeErrorInfo(perriErrorInfo);

```

WinFreeErrorInfo Parameter - perriErrorInfo

perriErrorInfo ([PERRINFO](#)) - input
 Error-information block whose memory is to be released.

WinFreeErrorInfo Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE

Successful completion

FALSE

perriErrorInfo is not an error-information block for the current thread.

WinFreeErrorInfo - Parameters

perriErrorInfo ([PERRINFO](#)) - input
Error-information block whose memory is to be released.

rc ([BOOL](#)) - returns
Success indicator.

TRUE

Successful completion

FALSE

perriErrorInfo is not an error-information block for the current thread.

WinFreeFileDialogList

WinFreeFileDialogList - Syntax

This function frees the storage allocated by the file dialog when the dialog flag is set.

```
#define INCL_winstdfile
#include <os2.h>

PAPSZ    papszFQFilename; /* Pointer to a table of pointers of fully-qualified file names returned by the dia
BOOL     rc;              /* Success indicator. */

rc = WinFreeFileDialogList(papszFQFilename);
```

WinFreeFileDialogList Parameter - papszFQFilename

papszFQFilename ([PAPSZ](#)) - input

Pointer to a table of pointers of fully-qualified file names returned by the dialog.

WinFreeFileDialogList Return Value - rc

rc ([BOOL](#)) - returns

Success indicator.

TRUE

	Successful completion.
FALSE	Error occurred.

WinFreeFileDlgList - Parameters

papszFQFilename ([PAPSZ](#)) - input

Pointer to a table of pointers of fully-qualified file names returned by the dialog.

rc ([BOOL](#)) - returns

Success indicator.

TRUE

Successful completion.

FALSE

Error occurred.

WinFreeFileDlgList - Remarks

When the style flag is set and the user selects one or more files from the file name list box, the fully-qualified file names of the selected files are returned in the field of the [FILEDLG](#) structure. After the application retrieves all of the information it needs from the array, it should call WinFreeFileDlgList to free the storage.

WinFreeFileDlgList - Example Code

This example uses the WinFreeFileDlgList function to deallocate the table of file name pointers returned by the [WinFileDlg](#) function when the field of the [FILEDLG](#) structure.

```
#define INCL_WINSTDFILE /* Window Standard File Functions */
#include <os2.h>

BOOL fSuccess; /* Success indicator */
FILEDLG pfdFiledlg; /* File dialog info structure */
HWND hwndMain; /* Window that owns the file dialog */
HWND hwndDlg; /* File dialog window */

/*****
/* initialize FILEDLG structure
*****/
pfdFiledlg.cbSize = sizeof(FILEDLG); /* Size of structure */
pfdFiledlg.fl = FDS_MULTIPLESEL | FDS_HELPBUTTON | FDS_CENTER |
                FDS_OPEN_DIALOG; /* FDS_* flags

/*****
/* Set remaining fields here
*****/
.
.

WinGetClipPS

WinGetClipPS - Syntax

This method obtains a clipped cache presentation space.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HWND     hwnd;           /* Handle of window for which the presentation space is required. */
HWND     hwndClipWindow; /* Handle of window for clipping. */
ULONG    ulClipflags;    /* Clipping control flags. */
HPS      hps;            /* Presentation-space handle that can be used for drawing. */

hps = WinGetClipPS(hwnd, hwndClipWindow, ulClipflags);
```

WinGetClipPS Parameter - hwnd

hwnd (**HWND**) - input
Handle of window for which the presentation space is required.

WinGetClipPS Parameter - hwndClipWindow

hwndClipWindow (**HWND**) - input
Handle of window for clipping.

Values to be specified can be one of the following:

- HWND_BOTTOM**
Clip the last window in the sibling chain and continue clipping until the next window is *hwnd* or NULLHANDLE.
 - HWND_TOP**
Clip the first window in the sibling chain and continue clipping until the next window is *hwnd* or NULLHANDLE.
 - NULLHANDLE**
Clip all siblings to the window *hwnd*.
-

WinGetClipPS Parameter - ulClipflags

ulClipflags ([ULONG](#)) - input
Clipping control flags.

PSF_CLIPSIBLINGS
Clip out all siblings of *hwnd*.

PSF_CLIPCHILDREN
Clip out all children of *hwnd*.

PSF_CLIPUPWARDS
Taking *hwndClipWindow* as a reference window, clip out all sibling windows before *hwndClipWindow*. This value may not be used with PSF_CLIPDOWNWARDS.

PSF_CLIPDOWNWARDS
Taking *hwndClipWindow* as a reference window, clip out all sibling windows after *hwndClipWindow*. This value may not be used with PSF_CLIPUPWARDS.

PSF_LOCKWINDOWUPDATE
Calculate a presentation space that keeps a visible region even though output may be locked by the [WinLockWindowUpdate](#) function.

PSF_PARENTCLIP
Calculate a presentation space that uses the visible region of the parent of *hwnd* but with an origin calculated for *hwnd*.

WinGetClipPS Return Value - hps

hps ([HPS](#)) - returns
Presentation-space handle that can be used for drawing.

WinGetClipPS - Parameters

hwnd ([HWND](#)) - input
Handle of window for which the presentation space is required.

hwndClipWindow ([HWND](#)) - input
Handle of window for clipping.

Values to be specified can be one of the following:

HWND_BOTTOM
Clip the last window in the sibling chain and continue clipping until the next window is *hwnd* or NULLHANDLE.

HWND_TOP
Clip the first window in the sibling chain and continue clipping until the next window is *hwnd* or NULLHANDLE.

NULLHANDLE
Clip all siblings to the window *hwnd*.

ulClipflags ([ULONG](#)) - input
Clipping control flags.

PSF_CLIPSIBLINGS
Clip out all siblings of *hwnd*.

PSF_CLIPCHILDREN
Clip out all children of *hwnd*.

PSF_CLIPUPWARDS

Taking *hwndClipWindow* as a reference window, clip out all sibling windows before *hwndClipWindow*. This value may not be used with PSF_CLIPDOWNWARDS.

PSF_CLIPDOWNWARDS

Taking *hwndClipWindow* as a reference window, clip out all sibling windows after *hwndClipWindow*. This value may not be used with PSF_CLIPUPWARDS.

PSF_LOCKWINDOWUPDATE

Calculate a presentation space that keeps a visible region even though output may be locked by the [WinLockWindowUpdate](#) function.

PSF_PARENTCLIP

Calculate a presentation space that uses the visible region of the parent of *hwnd* but with an origin calculated for *hwnd*.

hps ([HPS](#)) - returns

Presentation-space handle that can be used for drawing.

WinGetClipPS - Remarks

The presentation space obtained by this method is a cache "micro-presentation space" present in the system. This can be used for simple drawing operations that do not depend on long-term data being stored in the presentation space.

When the application finishes using the clipped cache presentation space, it should destroy it using the [WinReleasePS](#) function.

WinGetClipPS - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)

An invalid window handle was specified.

WinGetClipPS - Example Code

This example responds to an application defined message (IDM_FILL) and uses WinGetClipPS to obtain and associate a cached presentation space with a window, where the PS is clipped to the children of the window.

```
#define INCL_WINWINDOWMGR      /* Window Manager Functions */
#include <os2.h>

HWND    hwnd;                /* PS window */
HWND    hwndClip;            /* clipping window */
RECT    rcl;                 /* update region */
HPS     hps;                 /* presentation-space handle */

case IDM_FILL:
    hps = WinGetClipPS(hwnd,    /* handle of the PS window */
                       hwndClip, /* handle of clipping window */
                       PSF_CLIPCHILDREN); /* clipping flags */
    WinFillRect(hps, &rcl, CLR_WHITE);
    WinReleasePS(hps);
```

WinGetCurrentTime

WinGetCurrentTime - Syntax

This function returns the current time.

```
#define INCL_WINTIMER /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB    hab;                /* Anchor-block handle. */
```

```
ULONG    ulTime; /* System-timer count. */  
  
ulTime = WinGetCurrentTime(hab);
```

WinGetCurrentTime Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinGetCurrentTime Return Value - ulTime

ulTime ([ULONG](#)) - returns
System-timer count.

The time is in milliseconds, from the system Initial Program Load (IPL). This is the same value as stored in the information segment.

WinGetCurrentTime - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

ulTime ([ULONG](#)) - returns
System-timer count.

The time is in milliseconds, from the system Initial Program Load (IPL). This is the same value as stored in the information segment.

WinGetDlgMsg

WinGetDlgMsg - Syntax

This function obtains a message from the application's queue associated with the specified dialog.

```
#define INCL_WINDIALOGS /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HWND  hwndDlg; /* Dialog-window handle. */
PQMSG pqmsg;   /* Message structure. */
BOOL  rc;      /* Continue message indicator. */

rc = WinGetDlgMsg(hwndDlg, pqmsg);
```

WinGetDlgMsg Parameter - hwndDlg

hwndDlg ([HWND](#)) - input
Dialog-window handle.

WinGetDlgMsg Parameter - pqmsg

pqmsg ([PQMSG](#)) - output
Message structure.

WinGetDlgMsg Return Value - rc

rc ([BOOL](#)) - returns
Continue message indicator.

TRUE
Message returned is not a [WM_QUIT](#) message and the dialog has not been dismissed.

FALSE
Message returned is a [WM_QUIT](#) message or the dialog has been dismissed.

WinGetDlgMsg - Parameters

hwndDlg ([HWND](#)) - input
Dialog-window handle.

pqmsg ([PQMSG](#)) - output
Message structure.

rc ([BOOL](#)) - returns
Continue message indicator.

TRUE
Message returned is not a [WM_QUIT](#) message and the dialog has not been dismissed.

FALSE
Message returned is a [WM_QUIT](#) message or the dialog has been dismissed.

WinGetDlgMsg - Remarks

This function enables a language that cannot support window procedures to provide the function of a modal dialog. The application creates a modeless dialog by the use of the [WinCreateDlg](#) or the [WinLoadDlg](#) functions and then issues this call to process messages only associated with the dialog.

The first time that this function is issued, the owner of the window specified by *hwndDlg* is disabled, thereby preventing input into windows other than the dialog. The owner of the window specified by *hwndDlg* is enabled when the [WinDismissDlg](#) function is issued either by the application or by the default dialog procedure.

If a [WM_QUIT](#) is encountered, WinGetDlgMsg itself issues a [WinDismissDlg](#) function, and posts the [WM_QUIT](#) message back to the queue so that the application main loop terminates in the normal way.

WinGetDlgMsg - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinGetDlgMsg - Example Code

This example uses `WinGetDlgMsg` to provide a modal dialog. When the user causes an open message (application defined `IDM_OPEN`), the dialog is loaded and displayed; `WinGetDlgMsg` then loops, grabbing messages from the queue and calling `MyDlgRoutine`-the dialog procedure which processes the messages-with the appropriate parameters. When the dialog issues a `WM_QUIT`, `WinGetDlgMsg` returns `FALSE` and the loop ends, returning control to owner window.

```

#define INCL_WINDIALOGS          /* Window Dialog Mgr Functions */
#include <os2.h>

HWND    hwnd;          /* owner window */
HWND    hwndDlg;        /* dialog window */
PQMSG    pqmsgmsg;      /* message */

case IDM_OPEN:
    hwndDlg = WinLoadDlg(HWND_DESKTOP, /* parent is desk top */
                        hwnd,          /* owner window handle */
                        NULL,          /* modeless dialog */
                        0L,            /* load from .EXE */
                        DLG_ID,        /* dialog resource id */
                        NULL);         /* no dialog parameters */

    /* loop and process dialog messages until WM_QUIT, calling
       dialog procedure for each message */
    while (WinGetDlgMsg(hwndDlg, &qmsg))
        MyDlgRoutine(hwndDlg, qmsg.msg, qmsg.mp1, qmsg.mp2);
    break;

MRESULT MyDlgRoutine(HWND hwndDlg, ULONG usMsgid, MPARAM mp1,
                    MPARAM mp2)
{
    switch(usMsgid)
    {
        /*
        .
        . process messages
        .
        */

        default:
            return (WinDefDlgProc(hwndDlg, usMsgid, mp1, mp2));
    }
}

```

WinGetErrorInfo

WinGetErrorInfo - Syntax

This function returns detailed error information.

```
#define INCL_WINERRORS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
PERRINFO perriErrorInfo; /* Error information. */

perriErrorInfo = WinGetErrorInfo(hab);
```

WinGetErrorInfo Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinGetErrorInfo Return Value - perriErrorInfo

perriErrorInfo ([PERRINFO](#)) - returns
Error information.

This structure contains information about the previous error code for the current thread:

NULL	No error information available
Other	Error information.

WinGetErrorInfo - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

perriErrorInfo ([PERRINFO](#)) - returns
Error information.

This structure contains information about the previous error code for the current thread:

NULL	No error information available
Other	Error information.

WinGetErrorInfo - Remarks

This function allocates a single private segment to contain the [ERRINFO](#) structure. All the pointers to string fields within the [ERRINFO](#) structure are offsets to memory within that segment.

The memory allocated by this function is not released until the returned pointer is passed to the [WinFreeErrorInfo](#) function.

WinGetErrorInfo - Related Functions

WinGetKeyState

WinGetKeyState - Syntax

This function returns the state of the key at the time that the last message obtained from the queue was posted.

```
#define INCL_WININPUT /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwndDesktop; /* Desktop-window handle. */
LONG    vkey;         /* Virtual key value. */
LONG    lKeyState;    /* Key state. */

lKeyState = WinGetKeyState(hwndDesktop, vkey);
```

WinGetKeyState Parameter - hwndDesktop

hwndDesktop (**HWND**) - input
Desktop-window handle.

HWND_DESKTOP	The desktop-window handle
Other	Specified desktop-window handle.

WinGetKeyState Parameter - vkey

vkey (**LONG**) - input
Virtual key value.

Contains the virtual key value in the low-order byte, and zero in the high-order byte. See remarks for possible values.

WinGetKeyState Return Value - lKeyState

lKeyState (**LONG**) - returns
Key state.

This value is the OR combination of the following bits:

0x0001	The key has been pressed an odd number of times since the system has been started.
0x8000	The key is down.

WinGetKeyState - Parameters

hwndDesktop ([HWND](#)) - input
Desktop-window handle.

HWND_DESKTOP
The desktop-window handle
Other
Specified desktop-window handle.

key ([LONG](#)) - input
Virtual key value.

Contains the virtual key value in the low-order byte, and zero in the high-order byte. See remarks for possible values.

lKeyState ([LONG](#)) - returns
Key state.

This value is the OR combination of the following bits:

0x0001
The key has been pressed an odd number of times since the system has been started.
0x8000
The key is down.

WinGetKeyState - Remarks

See also the [WinGetPhysKeyState](#) function. This function is used to determine whether a virtual key is up, down, or toggled.

This function can be used to obtain the state of the pointing device buttons with the VK_BUTTON1, VK_BUTTON2, and VK_BUTTON3 virtual key codes. The following are the possible values for the *key* parameter:

WinGetKeyState - Example Code

This example uses WinGetKeyState to check if mouse button 1 was depressed when a WM_TIMER message was received. A high pitched beep is emitted if it was depressed, and a low pitched beep if it was not.

```
#define INCL_WININPUT      /* Window Input functions */
#define INCL_DOSPROCESS    /* OS/2 Process functions */
#include <os2.h>

LONG   lKeyState;          /* Key state */
LONG   vkey;               /* Virtual key value */

case WM_TIMER:
    /* Get the key state of mouse button 1 */
    vkey = VK_BUTTON1;
    lKeyState = WinGetKeyState(HWND_DESKTOP, vkey);

    /* Emit a high pitched beep if mouse button 1 is depressed */
    /* when the timer message occurred; otherwise, emit a low */
    /* pitched beep */
    if (lKeyState & 0x8000)
        DosBeep(1000,100L);
    else
        DosBeep(200,100L);
```

WinGetLastError

WinGetLastError - Syntax

This function returns the error code set by the failure of a Presentation Manager function.

```
#define INCL_WINERRORS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
ERRORID  erridErrorCode; /* Last error code. */

erridErrorCode = WinGetLastError(hab);
```

WinGetLastError Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinGetLastError Return Value - erridErrorCode

erridErrorCode ([ERRORID](#)) - returns
Last error code.

The returned error code is a 32-bit quantity. The high order 16 bits is a severity code. The low order 16 bits is the error code.

See the Notes for more information on using the returned ERRORID value.

WinGetLastError - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

erridErrorCode ([ERRORID](#)) - returns
Last error code.

The returned error code is a 32-bit quantity. The high order 16 bits is a severity code. The low order 16 bits is the error code.

See the Notes for more information on using the returned ERRORID value.

WinGetLastError - Remarks

Returns the last nonzero error code, and sets the error code to zero.

The current error code is reset to zero.

In multiple thread applications where there are multiple anchor blocks, errors are stored in the anchor block created by the [WinInitialize](#) function of the thread invoking a call. The last error for the process and thread on which this function call is made will be returned.

The returned error code is a 32-bit quantity. The high order 16 bits is a severity code. The low order 16 bits is the error code.

The severity codes are defined as follows:

```
#define SEVERITY_NOERROR          0x0000
#define SEVERITY_WARNING         0x0004
#define SEVERITY_ERROR           0x0008
#define SEVERITY_SEVERE          0x000C
#define SEVERITY_UNRECOVERABLE   0x0010
```

Error codes are described in

Two macros have been defined to simplify extracting severity codes and error codes from the returned ERRORID value.

```
/* Extract severity from an errorid */
#define ERRORIDSEV(errid)          (HIUSHORT(errid))

/* Extract error number from an errorid */
#define ERRORIDERROR(errid)       (LOUSHORT(errid))
```

WinGetMaxPosition

WinGetMaxPosition - Syntax

The WinGetMaxPosition function fills an SWP structure with the maximized-window size and position.

```
#define INCL_WINFRAMEMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwnd;          /* Frame-window handle. */
PSWP    pswp;          /* Set window position structure. */
BOOL    fSuccess;      /* Success indicator. */

fSuccess = WinGetMaxPosition(hwnd, pswp);
```

WinGetMaxPosition Parameter - hwnd

hwnd (**HWND**) - input
Frame-window handle.

Identifies the window whose maximum size will be retrieved.

WinGetMaxPosition Parameter - pswp

pswp (**PSWP**) - output
Set window position structure.

Points to the SWP structure that retrieves the size and position of a maximized window.

The SWP_SIZE and SWP_MOVE indicators are set in this parameter on return from this call, implying that the parameters have been initialized.

WinGetMaxPosition Return Value - fSuccess

fSuccess (BOOL) - returns
Success indicator.

TRUE	Successful completion.
FALSE	Error occurred.

WinGetMaxPosition - Parameters

hwnd (HWND) - input
Frame-window handle.

Identifies the window whose maximum size will be retrieved.

pswp (PSWP) - output
Set window position structure.

Points to the SWP structure that retrieves the size and position of a maximized window.

The SWP_SIZE and SWP_MOVE indicators are set in this parameter on return from this call, implying that the parameters have been initialized.

fSuccess (BOOL) - returns
Success indicator.

TRUE	Successful completion.
FALSE	Error occurred.

WinGetMaxPosition - Example Code

This example uses WinGetMaxPosition to determine the maximized position for the window in response to a maximize message (WM_MINMAXFRAME), and then calls WinSetWindowPos to maximize the window to that position.

```
#define INCL_WINFRAMEMGR          /* Window Frame Functions */
#include <os2.h>

BOOL fSuccess;                  /* Success indicator */
HWND hwnd;                     /* window handle */
MPARAM mpParam1;               /* Parameter 1 (window position) */
PSWP pSwp;                     /* Set window position structure */

case WM_MINMAXFRAME:
    pSwp = (PSWP)PVOIDFROMMP(mpParam1);

    switch(pSwp->fl)
    {
        case SWP_MAXIMIZE:
            fSuccess = WinGetMaxPosition(hwnd, pSwp);
```

```

        WinSetWindowPos(hwnd, 0L,
        pSwp->x,          /* x pos */
        pSwp->y,          /* y pos */
        pSwp->cx,         /* x size */
        pSwp->cy,         /* y size */
        SWP_MAXIMIZE);   /* flags */
        break;
    }

WinGetMinPosition

WinGetMinPosition - Syntax

This function returns the position to which a window is minimized.

```

#define INCL_WINFRAMEMEMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwnd; /* Frame-window handle. */
PSWP      pswp; /* Set window position structure. */
PPOINTL   pptl; /* Preferred position. */
BOOL      rc;   /* Success indicator. */

rc = WinGetMinPosition(hwnd, pswp, pptl);

```

WinGetMinPosition Parameter - hwnd

hwnd (**HWND**) - input
Frame-window handle.

WinGetMinPosition Parameter - pswp

pswp (PSWP) - output
Set window position structure.

The SWP_SIZE and SWP_MOVE indicators are set in this parameter on return from this function, implying that the parameters have been initialized.

WinGetMinPosition Parameter - pptl

pptl (PPOINTL) - input
Preferred position.

- NULL
System is to choose the position
- Other
System is to choose the position nearest to the specified point.

WinGetMinPosition Return Value - rc

rc (BOOL) - returns
Success indicator.

- TRUE
Successful completion.

The WS_MINIMIZE style is set for *hwnd*. This enables the system to determine which other frame windows are minimized, during the enumeration process performed by this function.

Also, the window words QWS_XMINIMIZE and QWS_YMINIMIZE for *hwnd* are initialized. This enables the system to ensure that no windows that have been, or are being, minimized use the same position.
- FALSE
Error occurred.

WinGetMinPosition - Parameters

hwnd (HWND) - input
Frame-window handle.

pswp (PSWP) - output
Set window position structure.

The SWP_SIZE and SWP_MOVE indicators are set in this parameter on return from this function, implying that the parameters have been initialized.

pptl (PPOINTL) - input
Preferred position.

NULL

Other	System is to choose the position
	System is to choose the position nearest to the specified point.
rc (BOOL) - returns Success indicator.	
TRUE	Successful completion.
	The WS_MINIMIZE style is set for <i>hwnd</i> . This enables the system to determine which other frame windows are minimized, during the enumeration process performed by this function.
	Also, the window words QWS_XMINIMIZE and QWS_YMINIMIZE for <i>hwnd</i> are initialized. This enables the system to ensure that no windows that have been, or are being, minimized use the same position.
FALSE	Error occurred.

WinGetMinPosition - Remarks

This function chooses the position for a minimized window. It enumerates all the siblings of the specified window to determine the first available position.

WinGetMsg Parameter - hab

hab ([HAB](#)) - input

Anchor-block handle.

WinGetMsg Parameter - pqmsgmsg

pqmsgmsg ([PQMSG](#)) - output
Message structure.

WinGetMsg Parameter - hwndFilter

hwndFilter ([HWND](#)) - input
Window filter.

WinGetMsg Parameter - ulFirst

ulFirst ([ULONG](#)) - input
First message identity.

WinGetMsg Parameter - ulLast

ulLast ([ULONG](#)) - input
Last message identity.

WinGetMsg Return Value - rc

rc ([BOOL](#)) - returns
Continue message indicator.

TRUE

Message returned is not a [WM_QUIT](#) message

FALSE

Message returned is a [WM_QUIT](#) message.

WinGetMsg - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

pqmsgmsg ([PQMSG](#)) - output
Message structure.

hwndFilter ([HWND](#)) - input
Window filter.

ulFirst ([ULONG](#)) - input
First message identity.

ulLast ([ULONG](#)) - input
Last message identity.

rc ([BOOL](#)) - returns
Continue message indicator.

TRUE	Message returned is not a WM_QUIT message
FALSE	Message returned is a WM_QUIT message.

WinGetMsg - Remarks

If system or queue hooks are installed, they are called before this function returns.

rc is generally used to determine when to terminate the application's main loop and exit the program.

hwndFilter constrains the returned message to be for a specific window or its children. When *hwndFilter* is null, the returned message can be for any window. The message identity is restricted to the range of message identities specified by *ulFirst* and *ulLast* inclusive. When *ulFirst* and *ulLast* are both zero, any message satisfies the range constraint. When *ulFirst* is greater than *ulLast*, messages except those whose identities lie between *ulFirst* and *ulLast* are eligible to be returned. Messages that do not conform to the filtering criteria remain in the queue.

When *hwndFilter* is null, and *ulFirst* and *ulLast* are both zero, all messages are returned in the order that they were posted to the queue.

By using filtering, messages can be processed in an order that is different from the one in the queue. Filtering is used in situations where applications receive messages of a particular type, rather than having to deal with other types of message at an inconvenient point in the logic of the application. For example, when a "mouse down" message is received, filtering can be used to wait for the "mouse up" message without having to be concerned with receiving other messages.

These constants can also be used when filtering messages:

WM_MOUSEFIRST	Lowest value pointing device message
WM_MOUSELAST	Highest value pointing device message
WM_BUTTONCLICKFIRST	Lowest value pointing device button click message
WM_BUTTONCLICKLAST	Highest value pointing device button click message
WM_DDE_FIRST	Lowest value DDE message
WM_DDE_LAST	Highest value DDE message.

Great care must be taken if filtering is used, to ensure that a message that satisfies the specification of the filtering parameters can occur, otherwise this function cannot complete. For example, calling this function with *ulFirst* and *ulLast* equal to [WM_CHAR](#) and with *hwndFilter* set to a window handle that does not have the input focus, prevents this function from returning.

Keystrokes are passed to the [WinTranslateAccel](#) call, which implies that accelerator keys are translated into [WM_COMMAND](#) or [WM_SYSCOMMAND](#) messages, and so are not seen as [WM_CHAR](#) messages by the application.

Note: An application must be prepared to receive messages other than those documented in this publication. All messages that an application does not want to handle should be dispatched to the appropriate window procedure using the [WinDispatchMsg](#) function.

WinGetMsg - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinGetMsg - Example Code

This example uses WinGetMsg to continually loop and retrieve messages from the message queue until a WM_QUIT message occurs.

```
#define INCL_WINMESSAGEGR      /* Window Message Functions */
#define INCL_WINWINDOWMGR     /* Window Manager Functions */
#include <os2.h>
```

```

HAB      hab;           /* anchor-block handle          */
HMQ      hmq;           /* message queue handle      */
PQMSG    pqmsgmsg;      /* message                    */

hab = WinInitialize(0);          /* initialize PM */

hmq = WinCreateMsgQueue(hab, 0); /* create default size queue */

/*
.
.  initialize windows
.
*/

/* get and dispatch messages from queue */
while (WinGetMsg(hab, &qmsgmsg, 0, 0, 0))
    WinDispatchMsg(hab, &qmsgmsg);

```

WinGetNextWindow

WinGetNextWindow - Syntax

This function gets the window handle of the next window in a specified enumeration list.

```

#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HENUM    henum;          /* Enumeration handle. */
HWND     hwndNext;       /* Next window handle in enumeration list. */

hwndNext = WinGetNextWindow(henum);

```

WinGetNextWindow Parameter - henum

henum ([HENUM](#)) - input
Enumeration handle.

Returned by previous call to the [WinBeginEnumWindows](#) call.

WinGetNextWindow Return Value - hwndNext

hwndNext ([HWND](#)) - returns
Next window handle in enumeration list.

NULLHANDLE	Error occurred, <i>henum</i> was invalid, or all the windows have been enumerated.
Other	Next window handle.

WinGetNextWindow - Parameters

henum ([HENUM](#)) - input
Enumeration handle.

Returned by previous call to the [WinBeginEnumWindows](#) call.

hwndNext ([HWND](#)) - returns
Next window handle in enumeration list.

NULLHANDLE	Error occurred, <i>henum</i> was invalid, or all the windows have been enumerated.
Other	Next window handle.

WinGetNextWindow - Remarks

Enumeration starts with the topmost child window and then proceeds downward through the enumeration list, in z-order at the time the [WinBeginEnumWindows](#) was issued, until all the windows have been enumerated. At this point, the call returns `NULLHANDLE`. The enumeration then wraps and the handle of the topmost child window is returned on the next call. This function does not lock windows.

WinGetNextWindow - Errors

Possible returns from [WinGetLastError](#)

`PMERR_INVALID_HENUM` (0x101C)
An invalid enumeration handle was specified.

WinGetNextWindow - Example Code

This example moves through all the child windows in a enumeration list, using an enumeration handle provided by WinBeginEnumWindows; for each child window, the class name is queried and placed in a buffer.

```
#define INCL_WINWINDOWMGR          /* Window Manager Functions */
#include <os2.h>

HWND  hwndParent;          /* Handle of the window whose child windows
                           are to be enumerated */
HWND  hwndNext;            /* current enumeration handle */
HENUM  henum;              /* enumeration handle */
BOOL   fSuccess;           /* success indicator */
SHORT  sRetLen;            /* returned string length */
SHORT  sLength = 10;       /* string buffer length */
char   pchBuffer[10];      /* string buffer */

hwndParent = HWND_DESKTOP;

henum = WinBeginEnumWindows(hwndParent);

while ((hwndNext = WinGetNextWindow(henum)) != NULLHANDLE)
    sRetLen = WinQueryClassName(hwndNext, sLength, pchBuffer);

fSuccess = WinEndEnumWindows (henum);
```

WinGetPhysKeyState

WinGetPhysKeyState - Syntax

This function returns the physical key state.

```
#define INCL_WININPUT /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwndDeskTop; /* Desktop-window handle. */
LONG    sc;           /* Hardware scan code. */
LONG    lKeyState;    /* Key state. */

lKeyState = WinGetPhysKeyState(hwndDeskTop,
                               sc);
```

WinGetPhysKeyState Parameter - hwndDeskTop

hwndDeskTop (**HWND**) - input
Desktop-window handle.

HWND_DESKTOP	The desktop-window handle
Other	Specified desktop-window handle.

WinGetPhysKeyState Parameter - sc

sc (**LONG**) - input
Hardware scan code.

Contains the scan code value in the low-order byte, and zero in the high-order byte.

WinGetPhysKeyState Return Value - lKeyState

lKeyState (**LONG**) - returns
Key state.

This value is the OR combination of the following bits:

0x0001	The key has been pressed since the last time this function was issued, or since the system has been started if this is the first time the call has been issued.
0x8000	The key is down.

WinGetPhysKeyState - Parameters

hwndDesktop ([HWND](#)) - input
Desktop-window handle.

HWND_DESKTOP	The desktop-window handle
Other	Specified desktop-window handle.

sc ([LONG](#)) - input
Hardware scan code.

Contains the scan code value in the low-order byte, and zero in the high-order byte.

lKeyState ([LONG](#)) - returns
Key state.

This value is the OR combination of the following bits:

0x0001	The key has been pressed since the last time this function was issued, or since the system has been started if this is the first time the call has been issued.
0x8000	The key is down.

WinGetPhysKeyState - Remarks

This function returns information about the asynchronous (interrupt level) state of the virtual key indicated by the *sc* parameter.

This function returns the physical state of the key; it is not synchronized to the processing of input (see the [WinGetKeyState](#) function).

WinGetPhysKeyState - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinGetPhysKeyState - Example Code

This example uses `WinGetPhysKeyState` to check the current state of the caps lock key; if it is depressed, a high pitch beep is emitted, while a low pitch beep is emitted if it is not depressed.

```
#define INCL_WININPUT      /* Window Input functions */
#define INCL_DOSPROCESS    /* OS/2 Process functions */
#include <os2.h>

LONG   lKeyState;          /* Key state          */
LONG   lScancode;         /* Scan code value   */

/* Get the physical key state for the caps lock key */
lScancode = 0x3a;
lKeyState = WinGetPhysKeyState(HWND_DESKTOP, lScancode);

/* Emit the high pitched beep if the caps lock is currently depressed; */
/* otherwise, emit a low pitched beep                                */
if (lKeyState & 0x8000)
    DosBeep(1000,100L);
else
    DosBeep(200,100L);
```

WinGetPS

WinGetPS - Syntax

This method gets a cache presentation space.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HWND    hwnd; /* Handle of window for which the presentation space is required. */
HPS     hps; /* Presentation-space handle that can be used for drawing in the window. */

hps = WinGetPS(hwnd);
```

WinGetPS Parameter - hwnd

- hwnd (HWND)** - input
Handle of window for which the presentation space is required.
 - HWND_DESKTOP
The desktop-window handle; a presentation space for the whole of the desktop window is returned
 - Other
Handle of window for which the presentation space is required.

WinGetPS Return Value - hps

- hps (HPS)** - returns
Presentation-space handle that can be used for drawing in the window.

WinGetPS - Parameters

- hwnd (HWND)** - input
Handle of window for which the presentation space is required.
 - HWND_DESKTOP
The desktop-window handle; a presentation space for the whole of the desktop window is returned
 - Other
Handle of window for which the presentation space is required.
- hps (HPS)** - returns
Presentation-space handle that can be used for drawing in the window.

WinGetPS - Remarks

The presentation space created by this method is a cache "micro presentation space" present in the system. This can be used for simple drawing operations that do not depend on long-term data being stored in the presentation space.

The initial state of the presentation space is the same as that of a presentation space created using [GpiCreatePS](#). The color table is in default color index mode. The visible region associated with *hps* depends upon the window and class styles of *hwnd*:

Style	Visible region of presentation space
WS_CLIPCHILDREN	All child windows of the window are excluded.
WS_CLIPSIBLINGS	All the sibling windows of <i>hwnd</i> are excluded.
CS_PARENTCLIP	Is the same as that of the parent window of the window.
	The presentation space origin is established normally, that is, relative to the lower left of the window itself, not its parent.
	This style optimizes the use of the presentation space cache by minimizing the calculation of the visible region for child windows.

Any presentation space created by [WinGetPS](#) must be released by calling [WinReleasePS](#). This should be done before the application terminates.

Note: This call requires the presence of a message queue and should not be made until after the application's message queue has been created.

WinGetPS - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinGetPS - Example Code

This example processes an application-defined message (IDM_FILL). It calls WinGetPS to get a presentation space to the entire window. It gets the dimensions of the current window, fills the window, and calls WinReleasePS to release the presentation space.

```
#define INCL_WINWINDOWMGR      /* Window Manager Functions */
#include <os2.h>

HWND    hwnd;                /* parent window */
RECTL   rcl;                 /* update region */
HPS     hps;                 /* presentation-space handle */

case IDM_FILL:
    hps = WinGetPS(hwnd);     /* get presentation space for */
                               /* the entire window */

    WinQueryWindowRect(hwnd, &rcl); /* get window dimensions */

    WinFillRect(hps, &rcl, CLR_WHITE); /* clear entire window */

    WinReleasePS(hps);         /* release the presentation */
                               /* space */

    return 0L;
```

WinGetScreenPS

WinGetScreenPS - Syntax

This method returns a presentation space that can be used for drawing anywhere on the screen.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>
```

```

HWND    hwndDesktop; /* Desktop-window handle. */
HPS     hpsScreenPS; /* Presentation-space handle. */

hpsScreenPS = WinGetScreenPS(hwndDesktop);

```

WinGetScreenPS Parameter - hwndDesktop

hwndDesktop (**HWND**) - input
Desktop-window handle.

HWND_DESKTOP
The desktop-window handle

Other
Specified desktop-window handle.

WinGetScreenPS Return Value - hpsScreenPS

hpsScreenPS (**HPS**) - returns
Presentation-space handle.

A micro presentation space that can be used for drawing over the entire desktop window (the whole screen).

NULLHANDLE
hwndDesktop is not **HWND_DESKTOP** or a desktop window handle obtained from the [WinQueryDesktopWindow](#) function.

Other
Presentation space handle.

WinGetScreenPS - Parameters

hwndDesktop (**HWND**) - input
Desktop-window handle.

HWND_DESKTOP
The desktop-window handle

Other
Specified desktop-window handle.

hpsScreenPS (**HPS**) - returns
Presentation-space handle.

A micro presentation space that can be used for drawing over the entire desktop window (the whole screen).

NULLHANDLE
hwndDesktop is not **HWND_DESKTOP** or a desktop window handle obtained from the [WinQueryDesktopWindow](#) function.

Other

Presentation space handle.

WinGetScreenPS - Remarks

Take great care when using this method. The returned presentation space is not clipped to any of the other windows present on the screen. Thus it is possible to draw in regions belonging to windows of other threads and processes.

The [WinLockWindowUpdate](#) function should be used to avoid simultaneous updates to the same part of the screen. This does not cause the presentation space returned by this function to become clipped in any way. Care of the appearance of windows of other threads is still the responsibility of the user of the screen presentation space.

When the application finishes using the screen presentation space, it should be destroyed using the [WinReleasePS](#) call.

WinGetScreenPS - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

	Used by some applications to display a sizebox in the bottom-right corner of a frame window.

hbm ([HBITMAP](#)) - returns
System bit-map handle.

NULLHANDLE	Error occurred
Other	System bit-map handle.

WinGetSysBitmap - Remarks

The bit map returned can be used for any of the normal bit-map operations. This function provides a new copy of the system bit map each time it is called. The application should release any bit maps it gets with this function by using `GpiDeleteBitmap`.

WinGetSysBitmap - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)

An invalid window handle was specified.

PMERR_PARAMETER_OUT_OF_RANGE (0x1003)

The value of a parameter was not within the defined valid range for that parameter.

PMERR_RESOURCE_NOT_FOUND (0x100A)

The specified resource identity could not be found.

WinInflateRect

WinInflateRect - Syntax

This function expands a rectangle.

```

#define INCL_WINRECTANGLES /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;    /* Anchor-block handle. */
PRECTL   prcl;   /* Rectangle to be expanded. */
LONG     cx;     /* Horizontal expansion. */
LONG     cy;     /* Vertical expansion. */
BOOL     rc;     /* Success indicator. */

rc = WinInflateRect(hab, prcl, cx, cy);

```

WinInflateRect Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinInflateRect Parameter - prcl

prcl ([PRECTL](#)) - in/out
Rectangle to be expanded.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) can also be used, if supported by the language.

WinInflateRect Parameter - cx

cx ([LONG](#)) - input
Horizontal expansion.

WinInflateRect Parameter - cy

cy ([LONG](#)) - input
Vertical expansion.

WinInflateRect Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinInflateRect - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

prcl ([PRECTL](#)) - in/out
Rectangle to be expanded.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) can also be used, if supported by the language.

cx ([LONG](#)) - input
Horizontal expansion.

cy ([LONG](#)) - input
Vertical expansion.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinInflateRect - Remarks

This function adjusts the size of the rectangle by applying the *cx* parameter horizontally at both vertical edges and the *cy* parameter vertically at both horizontal edges.

The *cx* parameter is subtracted from the left and added to the right of the rectangle, and the *cy* parameter is subtracted from the bottom and added to the top of the rectangle.

If the values of the *cx* and *cy* parameters are both positive, the rectangle is enlarged and surrounds the original rectangle. Conversely, if both these values are negative, the rectangle is reduced in size and is inset with respect to the original rectangle.

WinInitialize

WinInitialize - Syntax

This function initializes the PM facilities for use by an application.

```

#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

ULONG fOptions; /* Initialization options. */
HAB hab;        /* Anchor-block handle. */

hab = WinInitialize(fOptions);

```

WinInitialize Parameter - fOptions

flOptions (**ULONG**) - input
Initialization options.

0

The initial state for newly created windows is that all messages for the window are available for processing by the application.

This is the only option available in PM.

WinInitialize Return Value - hab

hab (**HAB**) - returns
Anchor-block handle.

NULLHANDLE

An error occurred.

Other

Anchor-block handle.

WinInitialize - Parameters

flOptions (**ULONG**) - input
Initialization options.

0

The initial state for newly created windows is that all messages for the window are available for processing by the application.

This is the only option available in PM.

hab (**HAB**) - returns
Anchor-block handle.

NULLHANDLE

An error occurred.

Other

Anchor-block handle.

WinInitialize - Remarks

This must be the first PM call issued by any application thread using Presentation Manager facilities.

It returns *hab*, which is NULL if the initialization is not successful.

The operating system does not generally use the information supplied by the *hab* parameter to its calls; instead, it deduces it from the identity of the thread that is making the call. Thus an OS/2 application is not required to supply any particular value as the *hab* parameter. However, in order to be portable to other environments, an application must provide the *hab*, that is returned by the WinInitialize function of the thread, to any OS/2 function that requires it.

flOptions determines the initial state of message processing with respect to a created window.

WinInSendMessage

WinInSendMessage - Syntax

This function determines whether the current thread is processing a message sent by another thread.

```
#define INCL_WINMESSAGEGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB    hab; /* Anchor-block handle. */
BOOL   rc; /* Message-processing indicator. */

rc = WinInSendMessage(hab);
```

WinInSendMessage Parameter - hab

hab (**HAB**) - input
Anchor-block handle.

WinInSendMessage Return Value - rc

rc (**BOOL**) - returns
Message-processing indicator.

TRUE	Current thread is processing a message sent by another thread
FALSE	Current thread is not processing a message, or an error occurred.

WinInSendMessage - Parameters

hab (**HAB**) - input
Anchor-block handle.

rc (**BOOL**) - returns
Message-processing indicator.

TRUE	Current thread is processing a message sent by another thread
FALSE	Current thread is not processing a message, or an error occurred.

WinInSendMessage - Remarks

If the message is from another thread this function determines whether or not the message was initiated by the active thread. The "active thread" is the thread associated with the current active window. (See also the [WinIsThreadActive](#) function.)

Typically this function is used by applications to determine how to proceed with errors when the window processing the message is not the active window. For example, if the active window uses the [WinSendMsg](#) function to send a request for information to another window, the other window cannot become active until it returns control from the [WinSendMsg](#) function. The only methods an inactive window has to inform the user of an error are to create a message box (see [WinMessageBox](#)), or to flash a window (see [WinFlashWindow](#)).

This function can be used to tell if a function is being called recursively.

WinInsertLboxItem

WinInsertLboxItem - Syntax

This macro inserts text into a list box at index, index may be a LIT_ constant. The macro returns the actual index where it was inserted.

```

#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwndLbox; /* List box handle. */
LONG    index;    /* Index of the list box item. */
PSZ     psz;      /* Text to be inserted. */
LONG    lRetIndex; /* Actual index where it was inserted. */

lRetIndex = WinInsertLboxItem(hwndLbox, index,
                             psz);

```

WinInsertLboxItem Parameter - hwndLbox

hwndLbox ([HWND](#)) - input
List box handle.

WinInsertLboxItem Parameter - index

index (**LONG**) - input
Index of the list box item.

WinInsertLboxItem Parameter - psz

psz (**PSZ**) - input
Text to be inserted.

WinInsertLboxItem Return Value - IRetIndex

IRetIndex (**LONG**) - returns
Actual index where it was inserted.

WinInsertLboxItem - Parameters

hwndLbox (**HWND**) - input
List box handle.

index (**LONG**) - input
Index of the list box item.

psz (**PSZ**) - input
Text to be inserted.

IRetIndex (**LONG**) - returns
Actual index where it was inserted.

WinInsertLboxItem - Remarks

This macro is defined as:

```
#define WinInsertLboxItem(hwndLbox, index, psz) \
    ((LONG)WinSendMessage(hwndLbox, \
        LM_INSERTITEM, \
        MPFROMLONG(index), \
        MPFROMP(psz)))
```

This macro requires the existence of a message queue.

WinIntersectRect

WinIntersectRect - Syntax

This function calculates the intersection of the two source rectangles and returns the result in the destination rectangle.

```
#define INCL_WINRECTANGLES /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
PRECTL   pcrIDst;      /* Intersection rectangle. */
PRECTL   pcrISrc1;     /* First rectangle. */
PRECTL   pcrISrc2;     /* Second rectangle. */
BOOL      rc;          /* Success indicator. */

rc = WinIntersectRect(hab, pcrIDst, pcrISrc1,
                      pcrISrc2);
```

WinIntersectRect Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinIntersectRect Parameter - pcrIDst

pcrIDst ([PRECTL](#)) - output
Intersection rectangle.

Is the intersection of *pcrISrc1* and *pcrISrc2*.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) can also be used, if supported by the language.

WinIntersectRect Parameter - pcrISrc1

pcrISrc1 ([PRECTL](#)) - input
First rectangle.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) can also be used, if supported by the language.

WinIntersectRect Parameter - pcrISrc2

pcrISrc2 ([PRECTL](#)) - input
Second rectangle.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) can also be used, if supported by the language.

WinIntersectRect Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

- | | |
|-------|---|
| TRUE | Source rectangles intersect |
| FALSE | Source rectangles do not intersect, or an error occurred. |

WinIntersectRect - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

pcrIDst ([PRECTL](#)) - output
Intersection rectangle.

Is the intersection of *pcrISrc1* and *pcrISrc2*.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) can also be used, if supported by the language.

pcrISrc1 ([PRECTL](#)) - input
First rectangle.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) can also be used, if supported by the language.

pcrISrc2 ([PRECTL](#)) - input
Second rectangle.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) can also be used, if supported by the language.

rc ([BOOL](#)) - returns
Success indicator.

TRUE
Source rectangles intersect

FALSE
Source rectangles do not intersect, or an error occurred.

WinIntersectRect - Remarks

If there is no intersection, an empty rectangle is returned in *prclDst*.

WinInvalidateRect

WinInvalidateRect - Syntax

This function adds a rectangle to a window's update region.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwnd;           /* Handle of window whose update region is to be changed. */
PRECTL    pwrcl;          /* Update rectangle. */
BOOL      fIncludeChildren; /* Invalidation-scope indicator. */
BOOL      rc;             /* Success indicator. */

rc = WinInvalidateRect(hwnd, pwrcl, fIncludeChildren);
```

WinInvalidateRect Parameter - hwnd

hwnd (**HWND**) - input

Handle of window whose update region is to be changed.

HWND_DESKTOP

This function applies to the whole screen (or desktop).

Other

Handle of window whose update region is to be changed.

WinInvalidateRect Parameter - pwrcl

pwrcl (**PRECTL**) - input

Update rectangle.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) can also be used, if supported by the language.

NULL	The whole window is to be added into the window's update region.
Other	Rectangle to be added to the window's update region.

WinInvalidateRect Parameter - fIncludeChildren

fIncludeChildren ([BOOL](#)) - input
Invalidation-scope indicator.

TRUE	Include the descendants of <i>hwnd</i> in the invalid rectangle.
FALSE	Include the descendants of <i>hwnd</i> in the invalid rectangle, but only if the parent does not have a WS_CLIPCHILDREN style.

WinInvalidateRect Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinInvalidateRect - Parameters

hwnd ([HWND](#)) - input
Handle of window whose update region is to be changed.

HWND_DESKTOP	This function applies to the whole screen (or desktop).
Other	Handle of window whose update region is to be changed.

pwrcl ([PRECTL](#)) - input
Update rectangle.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) can also be used, if supported by the language.

NULL	The whole window is to be added into the window's update region.
Other	Rectangle to be added to the window's update region.

flIncludeChildren ([BOOL](#)) - input
Invalidation-scope indicator.

TRUE

Include the descendants of *hwnd* in the invalid rectangle.

FALSE

Include the descendants of *hwnd* in the invalid rectangle, but only if the parent does not have a WS_CLIPCHILDREN style.

rc ([BOOL](#)) - returns
Success indicator.

TRUE

Successful completion

FALSE

Error occurred.

WinInvalidateRect - Remarks

The update region is a subregion of a window that is deemed "invalid" or incorrect in visual terms and in need of redrawing.

If the window has a CS_SYNCPAINT style, it is redrawn during the processing of this function and the update region should be NULL on return from this function.

If the window has a WS_CLIPCHILDREN style with part of its update region overlapping child windows with a CS_SYNCPAINT style, those children are updated before this function returns.

This function should not be called in response to a [WM_PAINT](#) request for windows of style CS_SYNCPAINT. CS_SYNCPAINT means that windows are updated synchronously when invalidated, which generates a [WM_PAINT](#) message. Thus, invalidating the window in response to a [WM_PAINT](#) message would cause another invalidate, and another [WM_PAINT](#), and so on.

WinInvalidateRect - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

PMERR_INVALID_FLAG (0x1019)
An invalid bit was set for a parameter. Use constants defined by PM for options, and do not set any reserved bits.

WinInvalidateRegion

WinInvalidateRegion - Syntax

This function adds a region to a window's update region.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwnd;          /* Handle of window whose update region is to be changed. */
HRGN    hrgn;          /* Handle of the region to be added to the update region of the window. */
BOOL    fIncludeChildren; /* Invalidation-scope indicator. */
BOOL    rc;            /* Success indicator. */

rc = WinInvalidateRegion(hwnd, hrgn, fIncludeChildren);
```

WinInvalidateRegion Parameter - hwnd

hwnd (**HWND**) - input

Handle of window whose update region is to be changed.

HWND_DESKTOP

This function applies to the whole screen (or desktop).

Other

Handle of window whose update region is to be changed.

WinInvalidateRegion Parameter - hrgn

hrgn (**HRGN**) - input

Handle of the region to be added to the update region of the window.

NULLHANDLE

The whole window is to be added into the window's update region.

Other

Handle of the region to be added to the window's update region.

WinInvalidateRegion Parameter - fIncludeChildren

fIncludeChildren (**BOOL**) - input

Invalidation-scope indicator.

TRUE

FALSE	Include the descendants of <i>hwnd</i> in the invalid rectangle.
	Include the descendants of <i>hwnd</i> in the invalid rectangle, but only if the parent does not have a WS_CLIPCHILDREN style.

WinInvalidateRegion Return Value - rc

rc (BOOL) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinInvalidateRegion - Parameters

hwnd (HWND) - input
Handle of window whose update region is to be changed.

HWND_DESKTOP	This function applies to the whole screen (or desktop).
Other	Handle of window whose update region is to be changed.

hrgn (HRGN) - input
Handle of the region to be added to the update region of the window.

NULLHANDLE	The whole window is to be added into the window's update region.
Other	Handle of the region to be added to the window's update region.

IncludeChildren (BOOL) - input
Invalidation-scope indicator.

TRUE	Include the descendants of <i>hwnd</i> in the invalid rectangle.
FALSE	Include the descendants of <i>hwnd</i> in the invalid rectangle, but only if the parent does not have a WS_CLIPCHILDREN style.

rc (BOOL) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinInvalidateRegion - Remarks

The update region is a subregion of a window that is deemed "invalid" or incorrect in visual terms and is in need of redrawing.

If the window has a `CS_SYNCPAINT` style, it is redrawn during the processing of this function and the update region should be `NULL` on return from this function.

If the window has a `WS_CLIPCHILDREN` style with part of its update region overlapping child windows with a `CS_SYNCPAINT` style, those children are updated before this function returns.

This function should not be called in response to a [WM_PAINT](#) request for windows of style `CS_SYNCPAINT`. `CS_SYNCPAINT` means that windows are updated synchronously when invalidated, which generates a [WM_PAINT](#) message. Thus, invalidating the window in response to a [WM_PAINT](#) message would cause another invalidate, another [WM_PAINT](#), and so on.

WinInvalidateRegion - Errors

Possible returns from [WinGetLastError](#)

`PMERR_INVALID_HWND` (0x1001)
An invalid window handle was specified.

`PMERR_HRGN_BUSY` (0x2034)
An internal region busy error was detected. The region was locked by one thread during an attempt to access it from another thread.

`PMERR_INVALID_FLAG` (0x1019)
An invalid bit was set for a parameter. Use constants defined by PM for options, and do not set any reserved bits.

WinInvalidateRegion - Example Code

This example invalidates the entire window by adding the whole window to the window's update region using WinInvalidateRegion. This single call accomplishes the same as paired calls to WinQueryWindowRect and WinInvalidateRect. If less than the entire window is desired, the NULL value in the second parameter can be replaced with a region handle that corresponds to a subregion of the window.

```
#define INCL_WINWINDOWMGR      /* Window Manager Functions */
#include <os2.h>

HWND      hwnd;                /* window handle */

WinInvalidateRegion(hwnd, NULLHANDLE, 0);
```

WinInvertRect

WinInvertRect - Syntax

This function inverts a rectangular area.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HPS      hps;                /* Presentation-space handle. */
PRECTL   prclRect;          /* Rectangle to be inverted. */
BOOL      rc;                /* Success indicator. */

rc = WinInvertRect(hps, prclRect);
```

WinInvertRect Parameter - hps

hps ([HPS](#)) - input
Presentation-space handle.

The presentation space contains the rectangle to be inverted.

WinInvertRect Parameter - prclRect

prclRect ([PRECTL](#)) - input
Rectangle to be inverted.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) can also be used, if supported by the language.

WinInvertRect Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinInvertRect - Parameters

hps ([HPS](#)) - input
Presentation-space handle.

The presentation space contains the rectangle to be inverted.

prclRect ([PRECTL](#)) - input
Rectangle to be inverted.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) can also be used, if supported by the language.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinInvertRect - Remarks

Inversion is a logical-NOT operation and has the effect of flipping the bits of each pel.

WinIsChild

WinIsChild - Syntax

This function indicates if a window is a descendant of another window.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwnd;           /* Child-window handle. */
HWND    hwndParent;     /* Parent-window handle. */
BOOL    fRelated;       /* Related indicator. */

fRelated = WinIsChild(hwnd, hwndParent);
```

WinIsChild Parameter - hwnd

hwnd ([HWND](#)) - input
Child-window handle.

WinIsChild Parameter - hwndParent

hwndParent ([HWND](#)) - input
Parent-window handle.

WinIsChild Return Value - fRelated

fRelated ([BOOL](#)) - returns
Related indicator.

TRUE

Child window is a descendant of the parent window, or is equal to it

FALSE

Child window is not a descendant of the parent, or is an Object Window (even if *hwndParent* is specified as the desktop or `HWND_DESKTOP`), or an error occurred.

WinIsChild - Parameters

hwnd ([HWND](#)) - input
Child-window handle.

hwndParent ([HWND](#)) - input
Parent-window handle.

fRelated ([BOOL](#)) - returns
Related indicator.

TRUE

Child window is a descendant of the parent window, or is equal to it

FALSE

Child window is not a descendant of the parent, or is an Object Window (even if *hwndParent* is specified as the desktop or `HWND_DESKTOP`), or an error occurred.

WinIsChild - Errors

Possible returns from [WinGetLastError](#)

`PMERR_INVALID_HWND (0x1001)`
An invalid window handle was specified.

WinIsControlEnabled

WinIsControlEnabled - Syntax

This function returns the state (enabled/disabled) of the specified item in the dialog template within a dialog box.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwndDlg; /* Dialog window handle. */
USHORT  usId;    /* Identity of the specified item. */
BOOL    rc;      /* Enabled-state indicator. */

rc = WinIsControlEnabled(hwndDlg, usId);
```

WinIsControlEnabled Parameter - hwndDlg

hwndDlg (**HWND**) - input
Dialog window handle.

WinIsControlEnabled Parameter - usId

usId (**USHORT**) - input
Identity of the specified item.

WinIsControlEnabled Return Value - rc

rc (**BOOL**) - returns
Enabled-state indicator.

- | | |
|-------|-----------------------------|
| TRUE | Specified item is enabled. |
| FALSE | Specified item is disabled. |
-

WinIsControlEnabled - Parameters

hwndDlg (**HWND**) - input
Dialog window handle.

usId (**USHORT**) - input
Identity of the specified item.

rc (**BOOL**) - returns
Enabled-state indicator.

- | | |
|-------|-----------------------------|
| TRUE | Specified item is enabled. |
| FALSE | Specified item is disabled. |
-

WinIsControlEnabled - Remarks

This macro expands to:

```
#define WinIsControlEnabled(hwndDlg, usId)  
((BOOL)WinIsWindowEnabled(WinWindowFromID(hwndDlg, usId)))
```

This function requires the existence of a message queue.

WinIsMenuItemChecked

WinIsMenuItemChecked - Syntax

This function returns the state (checked/not checked) of the identified menu item.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND     hwndMenu; /* Menu window handle. */
USHORT   usId;     /* Identity of the menu item. */
BOOL     rc;       /* Checked-state indicator. */

rc = WinIsMenuItemChecked(hwndMenu, usId);
```

WinIsMenuItemChecked Parameter - hwndMenu

hwndMenu (**HWND**) - input
Menu window handle.

WinIsMenuItemChecked Parameter - usId

usId (**USHORT**) - input
Identity of the menu item.

WinIsMenuItemChecked Return Value - rc

rc (**BOOL**) - returns
Checked-state indicator.

TRUE	Menu item is checked.
FALSE	Menu item is not checked.

WinIsMenuItemChecked - Parameters

hwndMenu (**HWND**) - input
Menu window handle.

usId ([USHORT](#)) - input
Identity of the menu item.

rc ([BOOL](#)) - returns
Checked-state indicator.

TRUE	Menu item is checked.
FALSE	Menu item is not checked.

WinIsMenuItemChecked - Remarks

This macro expands to:

```
#define WinIsMenuItemChecked(hwndMenu, usId)
( (BOOL)WinSendMsg(hwndMenu,
    MM_QUERYITEMATTR,
    MPFROM2SHORT(usId, TRUE),
    MPFROM2SHORT(MIA_CHECKED)) )
```

This function requires the existence of a message queue.

rc = WinIsMenuItemEnabled(hwndMenu, usId);

```

WinIsMenuItemEnabled Parameter - hwndMenu

hwndMenu (**HWND**) - input
Menu window handle.

WinIsMenuItemEnabled Parameter - usId

usId (**USHORT**) - input
Identity of the menu item.

WinIsMenuItemEnabled Return Value - rc

rc (**BOOL**) - returns
Enabled-state indicator.

TRUE	Menu item is enabled.
FALSE	Menu item is disabled.

WinIsMenuItemEnabled - Parameters

hwndMenu (**HWND**) - input
Menu window handle.

usId (**USHORT**) - input
Identity of the menu item.

rc (**BOOL**) - returns
Enabled-state indicator.

TRUE	Menu item is enabled.
FALSE	Menu item is disabled.

WinIsMenuItemEnabled - Remarks

This macro expands to:

```
#define WinIsMenuItemEnabled(hwndMenu, usId)
( !(BOOL)WinSendMsg(hwndMenu,
    MM_QUERYITEMATTR,

WinIsRectEmpty

WinIsRectEmpty - Syntax

This function checks whether a rectangle is empty.

```
#define INCL_WINRECTANGLES /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;      /* Anchor-block handle. */
PRECTL   prclprc;  /* Rectangle to be checked. */
BOOL     rc;        /* Empty indicator. */

rc = WinIsRectEmpty(hab, prclprc);
```

WinIsRectEmpty Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinIsRectEmpty Parameter - prclprc

prclprc ([PRECTL](#)) - input
Rectangle to be checked.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) can also be used, if supported by the language.

WinIsRectEmpty Return Value - rc

rc ([BOOL](#)) - returns
Empty indicator.

- | | |
|-------|-------------------------|
| TRUE | Rectangle is empty |
| FALSE | Rectangle is not empty. |

WinIsRectEmpty - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

prclprc ([PRECTL](#)) - input
Rectangle to be checked.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) can also be used, if supported by the language.

rc ([BOOL](#)) - returns
Empty indicator.

- | | |
|-------|-------------------------|
| TRUE | Rectangle is empty |
| FALSE | Rectangle is not empty. |

WinIsRectEmpty - Remarks

A rectangle has area if its left edge coordinate is less than its right edge coordinate, and its bottom edge coordinate is less than its top edge

coordinate. An empty rectangle is one with no area.

WinIsSOMDDReady

WinIsSOMDDReady - Syntax

This function returns the state of the DSOM daemon (SOMDD), started by the Workplace Shell process using [WinRestartSOMDD](#).

```
#define INCL_WPCCLASS
#include <os2.h>

BOOL    fReady; /* SOMDD-state indicator. */

fReady = WinIsSOMDDReady();
```

WinIsSOMDDReady Return Value - fReady

fReady (BOOL) - returns
SOMDD-state indicator.

TRUE	SOMDD has been started by the Workplace Shell process.
FALSE	SOMDD has not been started by the Workplace Shell process.

WinIsSOMDDReady - Parameters

fReady (BOOL) - returns
SOMDD-state indicator.

TRUE	SOMDD has been started by the Workplace Shell process.
FALSE	SOMDD has not been started by the Workplace Shell process.

WinIsSOMDDReady - Remarks

This function returns the state of the DSOM daemon started only by the Workplace Shell process using a call to [WinRestartSOMDD](#). This does not include the status of the DSOM daemon if started by any other process.

Note: This function requires that the Presentation Manager Shell is up and running.

WinIsThreadActive

WinIsThreadActive - Syntax

This function determines whether the active window belongs to the calling execution thread.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>
```

```
HAB    hab; /* Anchor-block handle of calling thread. */
BOOL   rc; /* Active-window indicator. */

rc = WinIsThreadActive(hab);
```

WinIsThreadActive Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle of calling thread.

WinIsThreadActive Return Value - rc

rc ([BOOL](#)) - returns
Active-window indicator.

TRUE	Active window belongs to the calling thread
FALSE	Active window does not belong to the calling thread.

WinIsThreadActive - Parameters

hab ([HAB](#)) - input
Anchor-block handle of calling thread.

rc ([BOOL](#)) - returns
Active-window indicator.

TRUE	Active window belongs to the calling thread
FALSE	Active window does not belong to the calling thread.

WinIsWindow

WinIsWindow - Syntax

This function determines if a window handle is valid.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB     hab; /* Anchor-block handle. */
HWND    hwnd; /* Window handle. */
BOOL     rc; /* Validity indicator. */

rc = WinIsWindow(hab, hwnd);
```

WinIsWindow Parameter - hab

hab (**HAB**) - input
Anchor-block handle.

WinIsWindow Parameter - hwnd

hwnd (**HWND**) - input
Window handle.

WinIsWindow Return Value - rc

rc (**BOOL**) - returns
Validity indicator.

TRUE	Window handle is valid
FALSE	Window handle is invalid.

WinIsWindow - Parameters

hab (**HAB**) - input
Anchor-block handle.

hwnd (**HWND**) - input
Window handle.

rc (**BOOL**) - returns
Validity indicator.

TRUE

	Window handle is valid
FALSE	Window handle is invalid.

WinIsWindow - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinIsWindowEnabled

WinIsWindowEnabled - Syntax

This function returns the state (enabled/disabled) of a window.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwnd; /* Window handle. */
BOOL    rc;    /* Enabled-state indicator. */

rc = WinIsWindowEnabled(hwnd);
```

WinIsWindowEnabled Parameter - hwnd

hwnd ([HWND](#)) - input
Window handle.

WinIsWindowEnabled Return Value - rc

rc ([BOOL](#)) - returns
Enabled-state indicator.

TRUE

FALSE	Window is enabled.
	Window is disabled.

WinIsWindowEnabled - Parameters

hwnd ([HWND](#)) - input
Window handle.

rc ([BOOL](#)) - returns
Enabled-state indicator.

TRUE	Window is enabled.
FALSE	Window is disabled.

WinIsWindowEnabled - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinIsWindowShowing

WinIsWindowShowing - Syntax

This function determines whether any part of the window *hwnd* is physically visible.

```

#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HWND    hwnd; /* Window handle. */
BOOL    rc;    /* Showing state indicator. */

rc = WinIsWindowShowing(hwnd);

```

WinIsWindowShowing Parameter - hwnd

hwnd ([HWND](#)) - input

Window handle.

WinIsWindowShowing Return Value - rc

rc ([BOOL](#)) - returns
Showing state indicator.

TRUE

Some part of the window is displayed on the screen.

FALSE

The function returns FALSE in these situations:

- No part of the window is displayed on the screen
 - The window is disabled
 - The window update is disabled
-

WinIsWindowShowing - Parameters

hwnd ([HWND](#)) - input
Window handle.

rc ([BOOL](#)) - returns
Showing state indicator.

TRUE

Some part of the window is displayed on the screen.

FALSE

The function returns FALSE in these situations:

- No part of the window is displayed on the screen
 - The window is disabled
 - The window update is disabled
-

WinIsWindowShowing - Remarks

This function is useful for applications that constantly output new information. If value FALSE is returned (that is, no part of the window is physically visible), the application can choose not to redraw, since redrawing is not necessary.

If an application is using WinIsWindowShowing, it must issue the call every time it has new information that needs to be updated. If this is not done, invalid screen content could result. The alternative to this approach for a constantly-updating application that has new information is for it to invalidate its window and redraw within a [WinBeginPaint](#) - [WinEndPaint](#) sequence.

FALSE is returned if the PM session is not currently visible.

WinIsWindowShowing - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)

An invalid window handle was specified.

 - [WinValidateRect](#)
 - [WinValidateRegion](#)
-

WinIsWindowShowing - Example Code

This example uses WinIsWindowShowing to check if any part of the window is physically visible before causing a redraw of the window via WinInvalidateRect.

```
#define INCL_WINWINDOWMGR      /* Window Manager Functions */
#define INCL_WINFRAMEMGR      /* Window Frame Functions */
#include <os2.h>

HWND    hwnd;                /* Window handle */
RECT    rcl;                 /* Update region */

/* If any part of the window is visible, cause a redraw */
if (WinIsWindowShowing(hwnd))
{
    WinQueryUpdateRect(hwnd, &rcl);
    WinInvalidateRect(hwnd, /* Window to invalidate */
                      &rcl, /* Invalid rectangle */
                      FALSE); /* Do not include children */
}
```

WinIsWindowVisible

WinIsWindowVisible - Syntax

This function returns the visibility state of a window.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwnd; /* Window handle. */
BOOL    rc;    /* Visibility-state indicator. */

rc = WinIsWindowVisible(hwnd);
```

WinIsWindowVisible Parameter - hwnd

hwnd (**HWND**) - input
Window handle.

WinIsWindowVisible Return Value - rc

rc (**BOOL**) - returns
Visibility-state indicator.

- | | |
|-------|---|
| TRUE | Window and all its parents have the WS_VISIBLE style bit set on |
| FALSE | Window or one of its parents have the WS_VISIBLE style bit set off. |

WinIsWindowVisible - Parameters

hwnd ([HWND](#)) - input
Window handle.

rc ([BOOL](#)) - returns
Visibility-state indicator.

TRUE	Window and all its parents have the WS_VISIBLE style bit set on
FALSE	Window or one of its parents have the WS_VISIBLE style bit set off.

WinIsWindowVisible - Remarks

Because *rc* reflects only the values of WS_VISIBLE style bits, *rc* may be set to TRUE even if *hwnd* is totally obscured by other windows. Use [WinIsWindowShowing](#) to determine if any part of the window is actually visible.

WinIsWindowVisible - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinIsWPDServerReady

WinIsWPDServerReady - Syntax

This function returns the state of the Workplace Shell DSOM server.

```
#define INCL_WPCCLASS
#include <os2.h>

BOOL    fReady; /* DSOM server-state indicator. DSOM Server status. */

fReady = WinIsWPDServerReady();
```

WinIsWPDServerReady Return Value - fReady

fReady ([BOOL](#)) - returns
DSOM server-state indicator. DSOM Server status.

TRUE	Workplace Shell DSOM Server is ready.
FALSE	Workplace Shell DSOM Server is not ready.

WinIsWPDServerReady - Parameters

fReady ([BOOL](#)) - returns
DSOM server-state indicator. DSOM Server status.

TRUE	Workplace Shell DSOM Server is ready.
FALSE	Workplace Shell DSOM Server is not ready.

WinIsWPDServerReady - Remarks

This function returns the ready status of the Workplace Shell DSOM Server.

Note: This function requires that the PM Shell is up and running.

WinLoadAccelTable

WinLoadAccelTable - Syntax

This function loads an accelerator table.

```

#define INCL_WINACCELERATORS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;           /* Anchor-block handle. */
HMODULE   Resource;      /* Resource identity containing the accelerator table. */
ULONG     idAccelTable;  /* Accelerator-table identifier, within the resource file. */
HACCEL    haccelAccel;   /* Accelerator-table handle. */

haccelAccel = WinLoadAccelTable(hab, Resource,
                                idAccelTable);

```

WinLoadAccelTable Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinLoadAccelTable Parameter - Resource

Resource ([HMODULE](#)) - input
Resource identity containing the accelerator table.

Module handle returned by the DosLoadModule or DosQueryModuleHandle functions referencing a dynamic link library containing the resource or NULLHANDLE for the application's module.

WinLoadAccelTable Parameter - idAccelTable

idAccelTable ([ULONG](#)) - input
Accelerator-table identifier, within the resource file.

It must be greater or equal to 0 and less or equal to 0xFFFF.

WinLoadAccelTable Return Value - haccelAccel

haccelAccel ([HACCEL](#)) - returns
Accelerator-table handle.

WinLoadAccelTable - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

Resource ([HMODULE](#)) - input
Resource identity containing the accelerator table.

Module handle returned by the DosLoadModule or DosQueryModuleHandle functions referencing a dynamic link library containing the resource or NULLHANDLE for the application's module.

idAccelTable ([ULONG](#)) - input
Accelerator-table identifier, within the resource file.

It must be greater or equal to 0 and less or equal to 0xFFFF.

haccelAccel ([HACCEL](#)) - returns
Accelerator-table handle.

WinLoadAccelTable - Remarks

This function returns a different value when called twice in succession with the same parameter values.

The accelerator table is owned by the process from which this function is issued. It cannot be accessed directly from any other process. If it still exists when the process terminates, it is automatically deleted by the system.

WinLoadAccelTable - Errors

Possible returns from [WinGetLastError](#)

PMERR_RESOURCE_NOT_FOUND (0x100A)
The specified resource identity could not be found.

WinLoadDlg

WinLoadDlg - Syntax

This function creates a dialog window from the dialog template *idDlg* in *hmod* and returns the dialog window handle.

```

#define INCL_WINDIALOGS /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HWND      hwndParent;      /* Parent-window handle of the created dialog window. */
HWND      hwndOwner;       /* Requested owner-window handle of the created dialog window. */
PFNWNDP   pfnDlgProc;      /* Dialog procedure for the created dialog window. */
HMODULE    hmod;           /* Resource identity containing the dialog template. */
ULONG     idDlg;           /* Dialog-template identity within the resource file. */
PVOID     pCreateParams;   /* Pointer to application-defined data area. */
HWND      hwndDlg;         /* Dialog-window handle. */

hwndDlg = WinLoadDlg(hwndParent, hwndOwner,
                    pfnDlgProc, hmod, idDlg, pCreateParams);

```

WinLoadDlg Parameter - hwndParent

hwndParent ([HWND](#)) - input
Parent-window handle of the created dialog window.

HWND_DESKTOP	The desktop window
HWND_OBJECT	Object window
Other	Specified window.

WinLoadDlg Parameter - hwndOwner

hwndOwner ([HWND](#)) - input
Requested owner-window handle of the created dialog window.

The actual owner window is calculated using the algorithm specified below.

WinLoadDlg Parameter - pfnDlgProc

pfnDlgProc ([PFNWP](#)) - input
Dialog procedure for the created dialog window.

WinLoadDlg Parameter - hmod

hmod ([HMODULE](#)) - input
Resource identity containing the dialog template.

NULLHANDLE	Use the application's .EXE file.
Other	Module handle returned from the DosLoadModule or DosQueryModuleHandle functions.

WinLoadDlg Parameter - idDlg

idDlg ([ULONG](#)) - input
Dialog-template identity within the resource file.

It is also used as the identity of the created dialog window.

WinLoadDlg Parameter - pCreateParams

pCreateParams ([PVOID](#)) - input

Pointer to application-defined data area.

This is passed to the dialog procedure in the [WM_INITDLG](#) message.

This parameter MUST be a pointer rather than a long.

WinLoadDlg Return Value - hwndDlg

hwndDlg ([HWND](#)) - returns

Dialog-window handle.

NULL

Dialog window not created

Other

Dialog window handle.

WinLoadDlg - Parameters

hwndParent ([HWND](#)) - input

Parent-window handle of the created dialog window.

HWND_DESKTOP

The desktop window

HWND_OBJECT

Object window

Other

Specified window.

hwndOwner ([HWND](#)) - input

Requested owner-window handle of the created dialog window.

The actual owner window is calculated using the algorithm specified below.

pfnDlgProc ([PFNWP](#)) - input

Dialog procedure for the created dialog window.

hmod ([HMODULE](#)) - input

Resource identity containing the dialog template.

NULLHANDLE

Use the application's .EXE file.

Other

Module handle returned from the DosLoadModule or DosQueryModuleHandle functions.

idDlg ([ULONG](#)) - input

Dialog-template identity within the resource file.

It is also used as the identity of the created dialog window.

pCreateParams ([PVOID](#)) - input

Pointer to application-defined data area.

This is passed to the dialog procedure in the [WM_INITDLG](#) message.

This parameter **MUST** be a pointer rather than a long.

hwndDlg (HWND) - returns
Dialog-window handle.

NULL	Dialog window not created
Other	Dialog window handle.

WinLoadDlg - Remarks

Unless window style `WS_VISIBLE` is specified for the dialog window in the `DIALOG` statement within the dialog template, the dialog window is created as an invisible window.

The dialog window owner may be modified, in order to ensure acceptable results if it is later processed as a modal dialog using the [WinProcessDlg](#) or [WinGetDlgMsg](#) functions. A search is made up the parent hierarchy, starting at the window specified by the *hwndOwner* parameter, until a child of the window specified by the *hwndParent* is found. If such a window exists, it is made the actual owner of the dialog. If no such window exists the actual owner of the dialog is set to `NULLHANDLE`.

This function returns immediately after creating the dialog window. A [WM_INITDLG \(Default Dialogs\)](#) message is sent to the dialog procedure before this function returns.

This function should not be used while pointing device capture is set (see [WinSetCapture](#)).

As each of the controls defined within the template of this dialog window is created during the processing of this function, the dialog procedure may receive various control notifications before this function returns.

A dialog window can be destroyed with the [WinDestroyWindow](#) function.

Because windows are created from the template, strings in the template are processed with [WinSubstituteStrings](#). Any resultant [WM_SUBSTITUTESTRING](#) messages are sent to the dialog procedure before this function returns.

When the child windows of the dialog are created, the [WinSubstituteStrings](#) function is used to allow the child windows to perform text substitutions in their window text. If any of the child window text strings contain the percent (%) substitution character, there is an upper limit of 256 on the length of the text string, after it is returned from the substitution.

If a dialog template (typically compiled using the resource compiler) references another resource (for example an icon resource for an icon static control), this function always searches for that resource in the .EXE file. If an application wishes to keep resources referenced by a dialog template in a .DLL library, these resources must be loaded by an explicit function call during the processing of the [WM_INITDLG](#) message.

Note: In general, it is better to create the dialog window invisible as this allows for optimization. In particular, an experienced user can type ahead, anticipating the processing in the dialog window.

In this instance, there may be no need to display the dialog window at all, as the user might have finished the interaction before the window can be displayed.

This is in fact how the [WinProcessDlg](#) function works; it does not display the dialog window while there are still [WM_CHAR](#) messages in the input queue, but allows these to be processed first.

WinLoadDlg - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

PMERR_INVALID_INTEGER_ATOM (0x1016)
The specified atom is not a valid integer atom.

PMERR_INVALID_ATOM_NAME (0x1015)
An invalid atom name string was passed.

PMERR_ATOM_NAME_NOT_FOUND (0x1017)
The specified atom name is not in the atom table.

PMERR_RESOURCE_NOT_FOUND (0x100A)
The specified resource identity could not be found.

WinLoadDlg - Example Code

This example uses WinLoadDlg to load a dialog template from the application's .EXE file.

```
#define INCL_WINDIALOGS      /* Window Dialog Mgr Functions */
#include <os2.h>

HWND  hwndOwner;           /* owner window */
HWND  hwndDlg;             /* Dialog-window handle */
PFNWP GenericDlgProc;      /* dialog process */

hwndDlg = WinLoadDlg(hwndDesktop, /* parent is desk top */
                    hwndOwner,    /* owner is main frame */
                    GenericDlgProc, /* dialog procedure */
                    0L,           /* load from resource file */
                    DLG_ID,       /* dialog resource id */
                    NULL);        /* no dialog parameters */
```

WinLoadFileIcon

WinLoadFileIcon - Syntax

This function returns a pointer to an icon which is associated with the file specified by *pszFileName*.

```
#define INCL_WINWORKPLACE
#include <os2.h>

PSZ      pszFileName; /* Pointer to file name. */
BOOL     fPrivate;    /* Icon usage flag. */
HPOINTER hIcon;       /* Icon handle. */

hIcon = WinLoadFileIcon(pszFileName, fPrivate);
```

WinLoadFileIcon Parameter - pszFileName

pszFileName ([PSZ](#)) - input
Pointer to file name.

A pointer to a zero-terminated string which contains the name of the file whose icon will be loaded.

WinLoadFileIcon Parameter - fPrivate

fPrivate ([BOOL](#)) - input

Icon usage flag.

TRUE

A private copy of this icon is requested. This flag should be used if the application needs to modify the icon.

FALSE

A shared pointer to this icon is requested. This flag should be used if application needs to display the icon without modifying it. This should be used whenever possible to optimize system resource use.

WinLoadFileIcon Return Value - hIcon

hIcon (**HPOINTER**) - returns
Icon handle.

NULL

Error occurred.

OTHER

Handle to an icon.

WinLoadFileIcon - Parameters

pszFileName (**PSZ**) - input
Pointer to file name.

A pointer to a zero-terminated string which contains the name of the file whose icon will be loaded.

fPrivate (**BOOL**) - input
Icon usage flag.

TRUE

A private copy of this icon is requested. This flag should be used if the application needs to modify the icon.

FALSE

A shared pointer to this icon is requested. This flag should be used if application needs to display the icon without modifying it. This should be used whenever possible to optimize system resource use.

hIcon (**HPOINTER**) - returns
Icon handle.

NULL

Error occurred.

OTHER

Handle to an icon.

WinLoadFileIcon - Remarks

The icon will be retrieved in the following order until an icon has been found:

- .ICON extended attribute
- .ICO file in same directory with same prefix
- Application specific icon (if PM executable or MS Windows* executable)

- PM application icon (if PM executable)
- MS Windows* application icon (if MS Windows* application executable)
- OS/2 application icon (if OS/2 full-screen only executable)
- OS/2 window icon (if OS/2 window compatible executable)
- DOS windowed application icon (if DOS windowed executable)
- Program application (if unknown type executable)
- Data icon specified by associated application
- Data icon of associated application
- Data file icon (if not program or directory)
- Directory icon (if directory)

The [HPOINTER](#) returned in *Private* should be freed by the caller via [WinFreeFileIcon](#) when it is no longer being used.

WinLoadHelpTable

WinLoadHelpTable - Syntax

This function identifies the module handle and identity of the help table to the instance of the Help Manager.

```
#define INCL_WINHELP /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwndHelpInstance; /* Handle of an instance of the Help Manager. */
ULONG      idHelpTable;     /* Identity of the help table. */
HMODULE     Module;         /* Handle of the module which contains the help table and help subtable resource. */
BOOL       rc;              /* Success indicator. */

rc = WinLoadHelpTable(hwndHelpInstance, idHelpTable,
    Module);
```

WinLoadHelpTable Parameter - hwndHelpInstance

hwndHelpInstance ([HWND](#)) - input
Handle of an instance of the Help Manager.

This is the handle returned by the [WinCreateHelpInstance](#) call.

WinLoadHelpTable Parameter - idHelpTable

idHelpTable ([ULONG](#)) - input
Identity of the help table.

It must be greater or equal to 0 and less or equal to 0xFFFF.

WinLoadHelpTable Parameter - Module

Module ([HMODULE](#)) - input
Handle of the module which contains the help table and help subtable resources.

- NULLHANDLE Use the resources file for the application.
- Other The module handle returned by the DosLoadModule or DosQueryModuleHandle call referencing a dynamic-link library containing the help resources.

WinLoadHelpTable Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

- TRUE Successful completion
- FALSE Error occurred.

WinLoadHelpTable - Parameters

hwndHelpInstance ([HWND](#)) - input
Handle of an instance of the Help Manager.

This is the handle returned by the [WinCreateHelpInstance](#) call.

idHelpTable ([ULONG](#)) - input
Identity of the help table.

It must be greater or equal to 0 and less or equal to 0xFFFF.

Module ([HMODULE](#)) - input
Handle of the module which contains the help table and help subtable resources.

NULLHANDLE	Use the resources file for the application.
Other	The module handle returned by the DosLoadModule or DosQueryModuleHandle call referencing a dynamic-link library containing the help resources.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinLoadHelpTable - Remarks

An application specifies or changes the handle of the module which contains the help table or the identity of the help table.

This function corresponds to the [HM_LOAD_HELP_TABLE](#) message that identifies the identifier of a help table and the handle of the module which contains the help table and its associated help subtables.

WinLoadLibrary

WinLoadLibrary - Syntax

This function makes the library available to the application.

```
#define INCL_WINLOAD /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>
```

```
HAB      hab;           /* Anchor-block handle. */
PSZ      pszLibname;    /* Library name. */
HLIB     hlibLibhandle; /* Library handle. */

hlibLibhandle = WinLoadLibrary(hab, pszLibname);
```

WinLoadLibrary Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinLoadLibrary Parameter - pszLibname

pszLibname ([PSZ](#)) - input
Library name.

WinLoadLibrary Return Value - hlibLibhandle

hlibLibhandle ([HLIB](#)) - returns
Library handle.

NULLHANDLE	Library not successfully loaded
Other	Library handle.

WinLoadLibrary - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

pszLibname ([PSZ](#)) - input
Library name.

hlibLibhandle ([HLIB](#)) - returns
Library handle.

NULLHANDLE	Library not successfully loaded
Other	Library handle.

WinLoadLibrary - Remarks

This function makes the library *pszLibname* (containing procedures, or resources, or both) available to the application. All of the dynamic link libraries have the .DLL filename extension by default.

WinLoadMenu

WinLoadMenu - Syntax

This function creates a menu window from the menu template *idMenu* from *hmod*, and returns in *hwndMenu* the window handle for the created window.

```
#define INCL_WINMENUS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwndFrame; /* Owner- and parent-window handle. */
HMODULE    hmod;      /* Resource identifier. */
ULONG      idMenu;    /* Menu identifier within the resource file. */
HWND      hwndMenu;   /* Menu-window handle. */

hwndMenu = WinLoadMenu(hwndFrame, hmod, idMenu);
```

WinLoadMenu Parameter - hwndFrame

hwndFrame (**HWND**) - input
Owner- and parent-window handle.

HWND_DESKTOP	The desktop window
HWND_OBJECT	Object window
Other	Specified window.

WinLoadMenu Parameter - hmod

hmod (**HMODULE**) - input
Resource identifier.

NULLHANDLE	The resource is in the .EXE file of the application.
Other	The module handle returned by the DosLoadModule or DosQueryModuleHandle call.

WinLoadMenu Parameter - idMenu

idMenu (**ULONG**) - input

Menu identifier within the resource file.

It must be greater or equal to 0 and less or equal to 0xFFFF.

WinLoadMenu Return Value - hwndMenu

hwndMenu ([HWND](#)) - returns
Menu-window handle.

WinLoadMenu - Parameters

hwndFrame ([HWND](#)) - input
Owner- and parent-window handle.

HWND_DESKTOP	The desktop window
HWND_OBJECT	Object window
Other	Specified window.

hmod ([HMODULE](#)) - input
Resource identifier.

NULLHANDLE	The resource is in the .EXE file of the application.
Other	The module handle returned by the DosLoadModule or DosQueryModuleHandle call.

idMenu ([ULONG](#)) - input
Menu identifier within the resource file.

It must be greater or equal to 0 and less or equal to 0xFFFF.

hwndMenu ([HWND](#)) - returns
Menu-window handle.

WinLoadMenu - Remarks

The menu window is created with its parent and owner set to *hwndFrame*, and with identity FID_MENU. If *hwndFrame* is HWND_OBJECT or a window handle returned from [WinQueryObjectWindow](#), the menu window is created as an object window.

Action bar menus are created as child windows of the frame window and are initially visible. Submenus are initially created as object windows that are owned by the window frame.

- [WinLoadMenu](#)
- [WinPopupMenu](#)

WinLoadMenu - Example Code

This example creates a menu window from the menu template (idMenuId) located in "RES.DLL" and returns a menu handle which is used by WinPopupMenu.

```
#define INCL_WINWINDOWMGR /* Window Manager Functions */
#define INCL_WINMENUS /* Window Menu Functions */
#include <os2.h>

HWND hwndMenu; /* Menu window */
HWND hwndOwner; /* Owner window */
HMODULE hmodDLL; /* resource handle */
ULONG idMenuId; /* Resource menu id */
BOOL fSuccess; /* Success indicator */
HWND hwndParent; /* Parent window */
ULONG flOptions; /* Pop-up menu options */

if (DosQueryModuleHandle("RES.DLL",&hmodDLL))
    hwndMenu = WinLoadMenu(hwndOwner, hmodDLL, idMenuId);

flOptions = PU_MOUSEBUTTON1DOWN |
            PU_KEYBOARD |
            PU_MOUSEBUTTON1;
fSuccess = WinPopupMenu(hwndParent,
                        hwndOwner,
                        hwndMenu,
                        0, 50, 0,
                        flOptions);
```

WinLoadMessage

WinLoadMessage - Syntax

This function loads a message from a resource, copies the message to the specified buffer, and appends a terminating null character.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;      /* Anchor-block handle. */
HMODULE  hmodMod;   /* Module handle. */
ULONG    ulId;      /* Message identifier. */
LONG     lcchMax;    /* Specifies the size of buffer. */
PSZ      pBuffer;   /* Points to the buffer that receives the message. */
LONG     lLength;    /* The length of the string returned. */

lLength = WinLoadMessage(hab, hmodMod, ulId,
                        lcchMax, pBuffer);
```

WinLoadMessage Parameter - hab

hab (**HAB**) - input
Anchor-block handle.

WinLoadMessage Parameter - hmodMod

hmodMod (**HMODULE**) - input
Module handle.

NULLHANDLE
Use the application's own resources file.

Other
Module handle returned by the DosLoadModule or DosQueryModuleHandle call referencing a dynamic-link library containing the resource.

WinLoadMessage Parameter - ulId

ulId (**ULONG**) - input
Message identifier.

It must be greater or equal to 0 and less or equal to 0xFFFF.

WinLoadMessage Parameter - lcchMax

lcchMax (**LONG**) - input
Specifies the size of buffer.

The maximum length of a string is 256 character.

WinLoadMessage Parameter - pBuffer

pBuffer (**PSZ**) - input
Points to the buffer that receives the message.

WinLoadMessage Return Value - ILength

ILength (**LONG**) - returns
The length of the string returned.

This excludes the terminating null, and has the following values:

0	Error
Other	A maximum value of (<i>lcchMax</i> -1).

WinLoadMessage - Parameters

hab (**HAB**) - input
Anchor-block handle.

hmodMod (**HMODULE**) - input
Module handle.

NULLHANDLE	Use the application's own resources file.
Other	Module handle returned by the DosLoadModule or DosQueryModuleHandle call referencing a dynamic-link library containing the resource.

uId (**ULONG**) - input
Message identifier.

It must be greater or equal to 0 and less or equal to 0xFFFF.

lcchMax (**LONG**) - input
Specifies the size of buffer.

The maximum length of a string is 256 character.

pBuffer (**PSZ**) - input
Points to the buffer that receives the message.

ILength (**LONG**) - returns

The length of the string returned.

This excludes the terminating null, and has the following values:

0	Error
Other	A maximum value of (<i>lcchMax</i> -1).

WinLoadMessage - Remarks

Message resources contain up to 16 messages each. The resource ID is calculated from the id parameter value passed to this function as follows:

```
resource ID = (id / 16) + 1
```

To save storage on disk and in memory, applications should number their message resources sequentially, starting at some multiple of 16.

WinLoadPointer

WinLoadPointer - Syntax

This function loads a pointer from a resource file into the system.

```

#define INCL_WINPOINTERS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwndDesktop; /* Desktop-window handle. */
HMODULE    Resource;    /* Resource identity containing the pointer definition. */
ULONG      idPointer;   /* Identifier of the pointer to be loaded. */
HPOINTER   hptr;        /* Pointer handle. */

hptr = WinLoadPointer(hwndDesktop, Resource,
    idPointer);

```

WinLoadPointer Parameter - hwndDesktop

hwndDesktop (HWND) - input
Desktop-window handle.

HWND_DESKTOP

Other	The desktop window
	Desktop-window handle returned by WinQueryDesktopWindow .

WinLoadPointer Parameter - Resource

Resource ([HMODULE](#)) - input
Resource identity containing the pointer definition.

NULLHANDLE	Use the resources file for the application.
------------	---

Other	Module handle returned by the DosLoadModule or DosQueryModuleHandle call referencing a dynamic-link library containing the resource.
-------	--

WinLoadPointer Parameter - idPointer

idPointer ([ULONG](#)) - input
Identifier of the pointer to be loaded.

It must be greater or equal to 0 and less or equal to 0xFFFF.

WinLoadPointer Return Value - hptr

hptr ([HPOINTER](#)) - returns
Pointer handle.

NULLHANDLE	Error has occurred
------------	--------------------

Other	Handle of loaded pointer.
-------	---------------------------

WinLoadPointer - Parameters

hwndDeskTop ([HWND](#)) - input
Desktop-window handle.

HWND_DESKTOP	The desktop window
--------------	--------------------

Other	Desktop-window handle returned by WinQueryDesktopWindow .
-------	---

Resource ([HMODULE](#)) - input

Resource identity containing the pointer definition.

NULLHANDLE

Use the resources file for the application.

Other

Module handle returned by the `DosLoadModule` or `DosQueryModuleHandle` call referencing a dynamic-link library containing the resource.

idPointer ([ULONG](#)) - input

Identifier of the pointer to be loaded.

It must be greater or equal to 0 and less or equal to 0xFFFF.

hptr ([HPOINTER](#)) - returns

Pointer handle.

NULLHANDLE

Error has occurred

Other

Handle of loaded pointer.

WinLoadPointer - Remarks

A new copy of the pointer is created each time this function is called. The pointer created by this function can be destroyed using the [WinDestroyPointer](#) function. To get one of the standard system pointers, use the [WinQuerySysPointer](#) function.

The pointer is owned by the process from which this function is issued. It cannot be accessed directly from any other process. If it still exists when the process terminates, it is automatically deleted by the system.

WinLoadPointer - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)

An invalid window handle was specified.

PMERR_RESOURCE_NOT_FOUND (0x100A)

The specified resource identity could not be found.

WinLoadProcedure

WinLoadProcedure - Syntax

This function loads the window or dialog procedure from a specified dynamic link library.

```
#define INCL_WINLOAD /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
HLIB     hlibLibhandle; /* Library handle. */
PSZ      pszProcname;  /* Procedure name. */
```

```
PFNWP Wndproc; /* Window-procedure identifier. */  
  
Wndproc = WinLoadProcedure(hab, hlibLibhandle,  
                           pszProcname);
```

WinLoadProcedure Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinLoadProcedure Parameter - hlibLibhandle

hlibLibhandle ([HLIB](#)) - input
Library handle.

WinLoadProcedure Parameter - pszProcname

pszProcname ([PSZ](#)) - input
Procedure name.

WinLoadProcedure Return Value - Wndproc

Wndproc ([PFNWP](#)) - returns
Window-procedure identifier.

NULL	Procedure not successfully loaded
Other	Window-procedure identifier.

WinLoadProcedure - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

hlibLibhandle ([HLIB](#)) - input

Library handle.

pszProcname ([PSZ](#)) - input
Procedure name.

Wndproc ([PFNWP](#)) - returns
Window-procedure identifier.

NULL	Procedure not successfully loaded
Other	Window-procedure identifier.

WinLoadProcedure - Remarks

This function loads the window or dialog procedure *pszProcname* from the library *hlibLibhandle*.

WinLoadProcedure - Related Functions

 - WinLoadProcedure
-

WinLoadProcedure - Example Code

This example loads the WndProc procedure, returning a pointer to the procedure, from the RES.DLL library, based on the library handle returned by WinLoadLibrary.

```
#define INCL_WINLOAD          /* Window Load Functions          */
#include <os2.h>

PFNWP  pWndproc;             /* procedure pointer          */
HAB     hab;                 /* anchor-block handle        */
HLIB     hlib;               /* library handle             */
char     pszLibname[10]="RES.DLL"; /* library name string        */
char     pszProcname[10]="WndProc"; /* procedure name string      */

/* load RES.DLL */
hlib = WinLoadLibrary(hab, pszLibname);

/* load WndProc */
pWndproc = WinLoadProcedure(hab, hlib, pszProcname);
```

WinLoadString

WinLoadString - Syntax

This function loads a string from a resource.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
HMODULE   Resource;     /* Resource identity containing the string. */
ULONG     idString;     /* String identifier. */
LONG      lBufferMax;   /* Size of buffer. */
PSZ       pszBuffer;    /* Buffer that is to receive the string. */
LONG      lLength;      /* The length of the string returned. */

lLength = WinLoadString(hab, Resource, idString,
                        lBufferMax, pszBuffer);
```

WinLoadString Parameter - hab

hab (**HAB**) - input
Anchor-block handle.

WinLoadString Parameter - Resource

- Resource** (**HMODULE**) - input
Resource identity containing the string.
- NULLHANDLE**
Use the application's own resources file.
 - Other**
Module handle returned by the DosLoadModule or DosQueryModuleHandle call referencing a dynamic-link library containing the resource.

WinLoadString Parameter - idString

idString (ULONG) - input
String identifier.

It must be greater or equal to 0 and less or equal to 0xFFFF.

WinLoadString Parameter - IBufferMax

IBufferMax (LONG) - input
Size of buffer.

The maximum length of a string is 256 characters.

WinLoadString Parameter - pszBuffer

pszBuffer (PSZ) - output
Buffer that is to receive the string.

WinLoadString Return Value - ILength

ILength (LONG) - returns
The length of the string returned.

This excludes the terminating null, and has the following values:

- 0
 - Other Error
 - A maximum value of (*IBufferMax*-1).
-

WinLoadString - Parameters

hab (HAB) - input
Anchor-block handle.

Resource (HMODULE) - input

Resource identity containing the string.

NULLHANDLE

Use the application's own resources file.

Other

Module handle returned by the `DosLoadModule` or `DosQueryModuleHandle` call referencing a dynamic-link library containing the resource.

idString ([ULONG](#)) - input
String identifier.

It must be greater or equal to 0 and less or equal to 0xFFFF.

IBufferMax ([LONG](#)) - input
Size of buffer.

The maximum length of a string is 256 characters.

pszBuffer ([PSZ](#)) - output
Buffer that is to receive the string.

lLength ([LONG](#)) - returns
The length of the string returned.

This excludes the terminating null, and has the following values:

0

Error

Other

A maximum value of $(IBufferMax-1)$.

WinLoadString - Remarks

This function loads a string resource identified by the *idString* and the *Resource* parameters into the *pszBuffer* parameter, and appends a terminating null character.

RT_STRING resources (string resources) contain up to 16 strings each. The resource ID is calculated from the *idString* passed to this function as follows:

```
resource ID = (idString / 16) + 1
```

To save storage on disk and in memory, applications should number their string resources sequentially, starting at some multiple of 16.

WinLoadString - Errors

Possible returns from [WinGetLastError](#)

PMERR_RESOURCE_NOT_FOUND (0x100A)
The specified resource identity could not be found.

WinLockPointerUpdate

WinLockPointerUpdate - Syntax

This function is specific to OS/2 Version 2.1 or higher.

This function causes the mouse pointer to change into the symbol described by *hptrNew* for the period of time indicated by *ulTimeInterval*.

```
#define INCL_WINPOINTERS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwndDesktop; /* Handle to the desktop window. */
HPOINTER   hptrNew;     /* Pointer handle to be displayed. */
ULONG      ulTimeInterval; /* Time interval. */
BOOL       rc;          /* Success indicator. */

rc = WinLockPointerUpdate(hwndDesktop, hptrNew,
                          ulTimeInterval);
```

WinLockPointerUpdate Parameter - hwndDesktop

hwndDesktop (**HWND**) - input
Handle to the desktop window.

WinLockPointerUpdate Parameter - hptrNew

hptrNew (**HPOINTER**) - input
Pointer handle to be displayed.

WinLockPointerUpdate Parameter - ulTimeInterval

ulTimeInterval (**ULONG**) - input
Time interval.

The time (0 to 65,535ms) during which changes to the mouse pointer shape will be locked out.

WinLockPointerUpdate Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful.
FALSE	An error occurred.

WinLockPointerUpdate - Parameters

hwndDesktop ([HWND](#)) - input
Handle to the desktop window.

hptrNew ([HPOINTER](#)) - input
Pointer handle to be displayed.

ulTimeInterval ([ULONG](#)) - input
Time interval.

The time (0 to 65,535ms) during which changes to the mouse pointer shape will be locked out.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful.
FALSE	An error occurred.

WinLockPointerUpdate - Remarks

The mouse remains fully functional during the lock time, however the pointer shape is not updated.

This function can be used to convey visual feedback to the user, that some mouse action has been recognized. For example, that a gesture has been recognized from the last few mouse movements.

WinLockupSystem

WinLockupSystem - Syntax

This function is specific to OS/2 Version 2.1 or higher.

This function locks up the system.

```
#define INCL_WINMESSAGEGR
#include <os2.h>

HAB hab; /* The application anchor block. */
BOOL rc; /* Return code. */

rc = WinLockupSystem(hab);
```

WinLockupSystem Parameter - hab

hab (**HAB**) - input
The application anchor block.

WinLockupSystem Return Value - rc

rc (**BOOL**) - returns
Return code.

TRUE	The system was successfully locked.
FALSE	An error occurred or the system was already in a locked state.

WinLockupSystem - Parameters

hab (**HAB**) - input
The application anchor block.

rc (**BOOL**) - returns
Return code.

TRUE	The system was successfully locked.
FALSE	An error occurred or the system was already in a locked state.

WinLockupSystem - Remarks

This function allows an application program to cause the system to lock up at any point in time. For example, a programmer might wish to lock up the system if any tampering is detected, such as a password being misspelled more than four times in a row.

In order to execute [WinUnlockSystem](#) after a WinLockupSystem has been called, the [WinUnlockSystem](#) must be called from a separate thread because WinLockupSystem will not return until a password has been entered from the keyboard.

The [LockupHook](#) hook allows a PM application to customize system lockups.

In order for the window to appear as the top most window on the lockup screen, the WS_CLIPSIBLINGS flag must be used for the *//Style* parameter in the [WinCreateWindow](#) or [WinCreateStdWindow](#) call.

WinLockVisRegions

WinLockVisRegions - Syntax

This function locks or unlocks the visible regions of all the windows on the screen, preventing any of the visible regions from changing.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwndDesktop; /* Desktop-window handle or HWND_DESKTOP. */
BOOL    fLock;        /* Indicates whether the visible regions are being locked or unlocked. */
BOOL    rc;           /* Success indicator. */

rc = WinLockVisRegions(hwndDesktop, fLock);
```

WinLockVisRegions Parameter - hwndDesktop

hwndDesktop ([HWND](#)) - input
Desktop-window handle or HWND_DESKTOP.

WinLockVisRegions Parameter - fLock

fLock ([BOOL](#)) - input
Indicates whether the visible regions are being locked or unlocked.

TRUE	Lock the visible regions
FALSE	Unlock the visible regions.

WinLockVisRegions Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful.
FALSE	An error occurred.

WinLockVisRegions - Parameters

hwndDesktop ([HWND](#)) - input
Desktop-window handle or `HWND_DESKTOP`.

fLock ([BOOL](#)) - input
Indicates whether the visible regions are being locked or unlocked.

TRUE	Lock the visible regions
FALSE	Unlock the visible regions.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful.
FALSE	An error occurred.

WinLockVisRegions - Remarks

This function is useful to threads that need to prevent window visible regions from changing while some screen operation, such as copying screen pels into a memory bit map, is being performed.

Any other thread that tries to alter the visible regions is blocked while the visible regions are locked. While the visible regions are locked, no messages must be sent and no functions called that can send messages.

Only one thread can lock the visible regions at any one time. The same thread can call `WinLockVisRegions` multiple times. A lock count is maintained by the system and is incremented each time a locking call is made, and decremented each time an unlocking call is made. The visible regions are unlocked when the count is zero.

Note: Locking the visible regions does not prevent painting of a window by another process.

WinLockVisRegions - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

-

WinLockVisRegions - Example Code

This example uses WinLockVisRegions to prevent any window's visible region from changing while a screen operation is executing. WinLockVisRegions is called before the screen operation to lock the visible regions and again after the operation to unlock the regions.

```
#define INCL_WINWINDOWMGR          /* Window Manager Functions */
#include <os2.h>

BOOL fSuccess;                    /* success indicator */

/* lock visible regions */
fSuccess = WinLockVisRegions(HWND_DESKTOP, TRUE);

/*
 *
 * . executing screen operation
 *
 */

/* unlock visible regions */
fSuccess = WinLockVisRegions(HWND_DESKTOP, FALSE);
```

WinLockWindowUpdate

WinLockWindowUpdate - Syntax

This function disables or enables output to a window and its descendants.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwndDeskTop;      /* Desktop handle of the screen containing the window to be locked. */
HWND    hwndLockUpdate;   /* Handle of window in which output is to be prevented. */
BOOL    rc;               /* Success indicator. */

rc = WinLockWindowUpdate(hwndDeskTop, hwndLockUpdate);
```

WinLockWindowUpdate Parameter - hwndDeskTop

hwndDeskTop ([HWND](#)) - input
Desktop handle of the screen containing the window to be locked.

HWND_DESKTOP	The desktop-window handle
Other	Specified desktop-window handle.

WinLockWindowUpdate Parameter - hwndLockUpdate

hwndLockUpdate ([HWND](#)) - input
Handle of window in which output is to be prevented.

NULLHANDLE	Enable output in the locked window and its descendants.
Other	Handle of the window in which output is to be prevented. Output is also prevented in the descendants of the

window.

WinLockWindowUpdate Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful operation.
FALSE	Error occurred.

WinLockWindowUpdate - Parameters

hwndDeskTop (**HWND**) - input
Desktop handle of the screen containing the window to be locked.

HWND_DESKTOP	The desktop-window handle
Other	Specified desktop-window handle.

hwndLockUpdate (**HWND**) - input
Handle of window in which output is to be prevented.

NULLHANDLE	Enable output in the locked window and its descendants.
Other	Handle of the window in which output is to be prevented. Output is also prevented in the descendants of the window.

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful operation.
FALSE	Error occurred.

WinLockWindowUpdate - Remarks

This function is used by threads that need to draw on an area of the screen over which they have no control. For example, the user interface sizing and moving calls use this call when drawing the shadow box, as a window is sized or moved.

All threads continue to run while the window is disabled; only output is prevented.

If one thread disables the window, other threads using this function are blocked until the first enables the window, although they can still receive messages.

This function does not prevent screen group switches, because these may be necessary to handle "hard errors" in other screen groups.

WinLockWindowUpdate - Example Code

This example disables output to a window and its children during a move operation (WM_MOVE) and then re-enables output once the move is finished.

```
#define INCL_WINWINDOWMGR          /* Window Manager Functions */
#include <os2.h>

HWND  hwndLock;          /* handle of window to be (un)locked */
BOOL  fSuccess;          /* success indicator */

case WM_MOVE:
    /* lock output */
    fSuccess = WinLockWindowUpdate(HWND_DESKTOP, hwndLock);

    /*
     *
     * . execute window move
     *
     */

    /* unlock output */
    fSuccess = WinLockWindowUpdate(HWND_DESKTOP, NULLHANDLE);
```

WinMakePoints

WinMakePoints - Syntax

This function converts points to graphics points.

```
#define INCL_WINRECTANGLES /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;    /* Anchor-block handle. */
PPOINTL  pwpt;   /* Points to be converted. */
ULONG    cwpt;   /* Number of points to be converted. */
BOOL      rc;    /* Success indicator. */

rc = WinMakePoints(hab, pwpt, cwpt);
```

WinMakePoints Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinMakePoints Parameter - pwpt

pwpt ([PPOINTL](#)) - in/out
Points to be converted.

The data type of these points after conversion is [POINTL](#).

WinMakePoints Parameter - cwpt

cwpt ([ULONG](#)) - input
Number of points to be converted.

Must be positive.

WinMakePoints Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinMakePoints - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

pwpt ([PPOINTL](#)) - in/out
Points to be converted.

The data type of these points after conversion is [POINTL](#).

cwpt ([ULONG](#)) - input
Number of points to be converted.

Must be positive.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinMakePoints - Remarks

This function converts the array of points from a [WPOINT](#) data structure into a [POINTL](#) data structure.

WinMakePoints - Example Code

This example calls WinMakePoints to convert a 3-element array of points from window points (WPOINT structure) to graphics points (POINTL structure).

```
#define INCL_WINRECTANGLES      /* Window Rectangle Functions */
#include <os2.h>

HAB      hab;                  /* anchor-block handle */
BOOL  fSuccess;                /* success indicator */
/* array of window points */
WPOINT pwptppt[3] = {0,0,0,0,20,0,50,0,100,0,60,0};

/* convert points */
fSuccess = WinMakePoints(hab, pwptppt, 3);
```

PRECTL   pwrc;   /* Rectangle to be converted. */
BOOL     rc;     /* Success indicator. */

rc = WinMakeRect(hab, pwrc);
```

WinMakeRect Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinMakeRect Parameter - pwrc

pwrc ([PRECTL](#)) - in/out
Rectangle to be converted.

The data type of the rectangle after conversion is [RECTL](#).

WinMakeRect Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinMakeRect - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

pwr ([RECTL](#)) - in/out
Rectangle to be converted.

The data type of the rectangle after conversion is [RECTL](#).

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinMakeRect - Remarks

This function converts a rectangle from a [WRECT](#) data structure into a [RECTL](#) data structure.

WinMapDlgPoints

WinMapDlgPoints - Syntax

This function maps points from dialog coordinates to window coordinates, or from window coordinates to dialog coordinates.

```
#define INCL_WINDIALOGS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwndDlg;          /* Dialog-window handle. */
PPOINTL   prgwptl;          /* Coordinate points to be mapped. */
ULONG      cwpt;            /* Number of coordinate points. */
BOOL      fCalcWindowCoords; /* Calculation control. */
BOOL      rc;               /* Coordinates-mapped indicator. */

rc = WinMapDlgPoints(hwndDlg, prgwptl, cwpt,
    fCalcWindowCoords);
```

WinMapDlgPoints Parameter - hwndDlg

hwndDlg ([HWND](#)) - input
Dialog-window handle.

WinMapDlgPoints Parameter - prgwptl

prgwptl ([PPOINTL](#)) - in/out
Coordinate points to be mapped.

The mapped points are substituted.

WinMapDlgPoints Parameter - cwpt

cwpt (**ULONG**) - input
Number of coordinate points.

WinMapDlgPoints Parameter - fCalcWindowCoords

fCalcWindowCoords (**BOOL**) - input
Calculation control.

TRUE

The points are in dialog coordinates and are to be mapped into window coordinates relative to the window specified by the *hwndDlg* parameter.

FALSE

The points are in window coordinates relative to the window specified by the *hwndDlg* parameter and are to be mapped into dialog coordinates.

WinMapDlgPoints Return Value - rc

rc (**BOOL**) - returns
Coordinates-mapped indicator.

TRUE

Coordinates successfully mapped

FALSE

Coordinates not successfully mapped.

WinMapDlgPoints - Parameters

hwndDlg (**HWND**) - input
Dialog-window handle.

prgwpptl (**PPOINTL**) - in/out
Coordinate points to be mapped.

The mapped points are substituted.

cwpt (**ULONG**) - input
Number of coordinate points.

fCalcWindowCoords ([BOOL](#)) - input
Calculation control.

TRUE	The points are in dialog coordinates and are to be mapped into window coordinates relative to the window specified by the <i>hwndDlg</i> parameter.
FALSE	The points are in window coordinates relative to the window specified by the <i>hwndDlg</i> parameter and are to be mapped into dialog coordinates.

rc ([BOOL](#)) - returns
Coordinates-mapped indicator.

TRUE	Coordinates successfully mapped
FALSE	Coordinates not successfully mapped.

WinMapDlgPoints - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinMapDlgPoints - Example Code

This example calls WinMapDlgPoints to map a point from dialog coordinates to window coordinates relative to the dialog window.

```
#define INCL_WINDIALOGS          /* Window Dialog Mgr Functions */
#include <os2.h>

HWND  hwndDlg;                  /* handle of dialog window */
BOOL  fSuccess;                 /* success indicator */
POINTL aptlPoint;              /* point to be mapped */

/* map point to relative window coordinates */
fSuccess = WinMapDlgPoints(hwndDlg, &aptlPoint, 1, TRUE);
```

WinMapWindowPoints

WinMapWindowPoints - Syntax

This function maps a set of points from a coordinate space relative to one window into a coordinate space relative to another window.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwndFrom; /* Handle of the window from whose coordinates points are to be mapped. */
HWND      hwndTo;   /* Handle of the window to whose coordinates points are to be mapped. */
PPOINTL   prgptl;   /* Points to be mapped to the new coordinate system. */
LONG      cwpt;     /* Number of points to be mapped. */
BOOL      rc;       /* Success indicator. */

rc = WinMapWindowPoints(hwndFrom, hwndTo,
                        prgptl, cwpt);
```

WinMapWindowPoints Parameter - hwndFrom

hwndFrom ([HWND](#)) - input

Handle of the window from whose coordinates points are to be mapped.

HWND_DESKTOP

Points are mapped from screen coordinates

Other

Points are mapped from window coordinates.

WinMapWindowPoints Parameter - hwndTo

hwndTo ([HWND](#)) - input

Handle of the window to whose coordinates points are to be mapped.

HWND_DESKTOP	Points are mapped into screen coordinates
Other	Points are mapped into window coordinates.

WinMapWindowPoints Parameter - prgptl

prgptl ([PPOINTL](#)) - in/out
Points to be mapped to the new coordinate system.

WinMapWindowPoints Parameter - cwpt

cwpt ([LONG](#)) - input
Number of points to be mapped.

prgptl can be a [RECTL](#) structure, in which case this parameter should have the value 2.

Note: This is not supported in all languages.

WinMapWindowPoints Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE Successful completion
FALSE Error occurred.

WinMapWindowPoints - Parameters

hwndFrom ([HWND](#)) - input
Handle of the window from whose coordinates points are to be mapped.

HWND_DESKTOP Points are mapped from screen coordinates
Other Points are mapped from window coordinates.

hwndTo ([HWND](#)) - input
Handle of the window to whose coordinates points are to be mapped.

HWND_DESKTOP Points are mapped into screen coordinates

Other

Points are mapped into window coordinates.

prgptl ([PPOINTL](#)) - in/out

Points to be mapped to the new coordinate system.

cwpt ([LONG](#)) - input

Number of points to be mapped.

prgptl can be a [RECTL](#) structure, in which case this parameter should have the value 2.

Note: This is not supported in all languages.

rc ([BOOL](#)) - returns

Success indicator.

TRUE

Successful completion

FALSE

Error occurred.

WinMapWindowPoints - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)

An invalid window handle was specified.

WinMapWindowPoints - Example Code

This example calls `WinMapWindowPoints` to map a mouse point on the desktop window to a mouse point in the client window and then checks whether the mouse pointer is inside the client area or not.

```
#define INCL_WINWINDOWMGR      /* Window Manager Functions */
#define INCL_WINRECTANGLES    /* Window Rectangle Functions */
#define INCL_WINPOINTERS      /* Window Pointer Functions */
#include <os2.h>

HAB      hab;           /* anchor-block handle */
HWND     hwndClient;    /* handle of client window */
BOOL     fSuccess;      /* success indicator */
POINTL   ptlMouse;      /* mouse pointer position */
RECTL    rclWork;       /* client area */

/* get current mouse pointer position */
WinQueryPointerPos(HWND_DESKTOP, &ptlMouse);

/* map from desktop to client window */
```

```
fSuccess = WinMapWindowPoints(HWND_DESKTOP, hwndClient,
                              &ptlMouse, 1);

/* check if new mouse position is inside the client area */
WinQueryWindowRect(hwndClient, &rclWork);
if (WinPtInRect(hab, &rclWork, &ptlMouse))
{
    /* pointer is in client area */
}
```

WinMessageBox

WinMessageBox - Syntax

This function creates, displays, and operates a message box window.

```
#define INCL_WINDIALOGS /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HWND    hwndParent; /* Parent-window handle of the created message-box window. */
HWND    hwndOwner;  /* Requested owner-window handle of the created message-box window. */
PSZ     pszText;     /* Message-box window message. */
PSZ     pszCaption;  /* Message-box window title. */
ULONG   idWindow;    /* Message-box window identity. */
ULONG   flStyle;     /* Message-box window style. */
ULONG   usResponse;  /* User-response value. */

usResponse = WinMessageBox(hwndParent, hwndOwner,
                          pszText, pszCaption, idWindow,
                          flStyle);
```

WinMessageBox Parameter - hwndParent

hwndParent ([HWND](#)) - input
Parent-window handle of the created message-box window.

[HWND_DESKTOP](#)
The message box is to be main window.

Other
Parent-window handle.

WinMessageBox Parameter - hwndOwner

hwndOwner ([HWND](#)) - input
Requested owner-window handle of the created message-box window.

The actual owner window is calculated using the algorithm specified in the description of the [WinLoadDlg](#) function.

WinMessageBox Parameter - pszText

pszText ([PSZ](#)) - input
Message-box window message.

The text of the message to be displayed within the message-box window. If multiple lines are required, carriage-return characters must be inserted into the text at appropriate points.

WinMessageBox Parameter - pszCaption

pszCaption ([PSZ](#)) - input
Message-box window title.

The text for the title should not be longer than 40 characters. If text longer than this is supplied, text centering is still performed, even though the beginning and end of the string are not visible.

NULL
The text Error is to be displayed as the title of the message-box window.

Other
The text to be displayed as the title of the message-box window.

WinMessageBox Parameter - idWindow

idWindow ([ULONG](#)) - input
Message-box window identity.

This value is passed to the HK_HELP hook if the [WM_HELP](#) message is received by the message-box window. It must be greater or equal to 0 and less or equal to 0xFFFF.

WinMessageBox Parameter - flStyle

flStyle ([ULONG](#)) - input
Message-box window style.

These values may be combined using the logical-OR operation but only one value can be taken from each of the following groups.

Button or Button Group

MB_OK	Message box contains an OK push button.
MB_OKCANCEL	Message box contains both OK and CANCEL push buttons.
MB_CANCEL	Message box contains a CANCEL push button.
MB_ENTER	Message box contains an ENTER push button.
MB_ENTERCANCEL	Message box contains both ENTER and CANCEL push buttons.
MB_RETRYCANCEL	Message box contains both RETRY and CANCEL push buttons.
MB_ABORTRETRYIGNORE	Message box contains ABORT, RETRY, and IGNORE push buttons.
MB_YESNO	Message box contains both YES and NO push buttons.
MB_YESNOCANCEL	Message box contains YES, NO, and CANCEL push buttons.

Help button

MB_HELP	Message box contains a HELP push button. When this is selected a WM_HELP message is sent to the window procedure of the message box.
---------	--

Color or Icon

MB_ERROR	Message box contains a small red circle with a red line across it.
MB_ICONASTERISK	Message box contains an information (i) icon.
MB_ICONEXCLAMATION	Message box contains an exclamation point (!) icon.
MB_ICONHAND	Message box contains a small red circle with a red line across it.
MB_ICONQUESTION	Message box contains a question mark (?) icon.
MB_INFORMATION	Message box contains an information (i) icon.
MB_NOICON	Message box is not to contain an icon.
MB_QUERY	Message box contains a question mark (?) icon.
MB_WARNING	Message box contains an exclamation point (!) icon.

Default action

MB_DEFBUTTON1	The first button is the default selection. This is the default case, if none of MB_DEFBUTTON1, MB_DEFBUTTON2, and MB_DEFBUTTON3 is specified.
MB_DEFBUTTON2	The second button is the default selection.
MB_DEFBUTTON3	The third button is the default selection.

Modality indicator

MB_APPLMODAL

Message box is application modal. This is the default case. Its owner is disabled; therefore, do not specify the owner as the parent if this option is used.

MB_SYSTEMMODAL

Message box is system modal.

Mobility indicator

MB_MOVEABLE

Message box is moveable.

The message box is displayed with a title bar and a system menu, which shows only the Move, Close, and Task Manager choices, which can be selected either by use of the pointing device or by accelerator keys.

If the user selects Close, the message box is removed and the *usResponse* is set to MBID_CANCEL, whether or not a cancel button existed within the message box.

WinMessageBox Return Value - usResponse

usResponse (**ULONG**) - returns
User-response value.

MBID_ENTER	ENTER push button was selected
MBID_OK	OK push button was selected
MBID_CANCEL	CANCEL push button was selected
MBID_ABORT	ABORT push button was selected
MBID_RETRY	RETRY push button was selected
MBID_IGNORE	IGNORE push button was selected
MBID_YES	YES push button was selected
MBID_NO	NO push button was selected
MBID_ERROR	Function not successful; an error occurred.

WinMessageBox - Parameters

hwndParent (**HWND**) - input
Parent-window handle of the created message-box window.

HWND_DESKTOP	The message box is to be main window.
Other	Parent-window handle.

hwndOwner (**HWND**) - input
Requested owner-window handle of the created message-box window.

The actual owner window is calculated using the algorithm specified in the description of the [WinLoadDlg](#) function.

pszText (PSZ) - input

Message-box window message.

The text of the message to be displayed within the message-box window. If multiple lines are required, carriage-return characters must be inserted into the text at appropriate points.

pszCaption (PSZ) - input

Message-box window title.

The text for the title should not be longer than 40 characters. If text longer than this is supplied, text centering is still performed, even though the beginning and end of the string are not visible.

NULL

The text Error is to be displayed as the title of the message-box window.

Other

The text to be displayed as the title of the message-box window.

idWindow (ULONG) - input

Message-box window identity.

This value is passed to the HK_HELP hook if the [WM_HELP](#) message is received by the message-box window. It must be greater or equal to 0 and less or equal to 0xFFFF.

flStyle (ULONG) - input

Message-box window style.

These values may be combined using the logical-OR operation but only one value can be taken from each of the following groups.

Button or Button Group

MB_OK	Message box contains an OK push button.
MB_OKCANCEL	Message box contains both OK and CANCEL push buttons.
MB_CANCEL	Message box contains a CANCEL push button.
MB_ENTER	Message box contains an ENTER push button.
MB_ENTERCANCEL	Message box contains both ENTER and CANCEL push buttons.
MB_RETRYCANCEL	Message box contains both RETRY and CANCEL push buttons.
MB_ABORTRETRYIGNORE	Message box contains ABORT, RETRY, and IGNORE push buttons.
MB_YESNO	Message box contains both YES and NO push buttons.
MB_YESNOCANCEL	Message box contains YES, NO, and CANCEL push buttons.

Help button

MB_HELP	Message box contains a HELP push button. When this is selected a WM_HELP message is sent to the window procedure of the message box.
---------	--

Color or Icon

MB_ERROR	Message box contains a small red circle with a red line across it.
MB_ICONASTERISK	Message box contains an information (i) icon.
MB_ICONEXCLAMATION	Message box contains an exclamation point (!) icon.
MB_ICONHAND	Message box contains a small red circle with a red line across it.
MB_ICONQUESTION	Message box contains a question mark (?) icon.
MB_INFORMATION	Message box contains an information (i) icon.

MB_NOICON	Message box is not to contain an icon.
MB_QUERY	Message box contains a question mark (?) icon.
MB_WARNING	Message box contains an exclamation point (!) icon.
Default action	
MB_DEFBUTTON1	The first button is the default selection. This is the default case, if none of MB_DEFBUTTON1, MB_DEFBUTTON2, and MB_DEFBUTTON3 is specified.
MB_DEFBUTTON2	The second button is the default selection.
MB_DEFBUTTON3	The third button is the default selection.
Modality indicator	
MB_APPLMODAL	Message box is application modal. This is the default case. Its owner is disabled; therefore, do not specify the owner as the parent if this option is used.
MB_SYSTEMMODAL	Message box is system modal.
Mobility indicator	
MB_MOVEABLE	<p>Message box is moveable.</p> <p>The message box is displayed with a title bar and a system menu, which shows only the Move, Close, and Task Manager choices, which can be selected either by use of the pointing device or by accelerator keys.</p> <p>If the user selects Close, the message box is removed and the <i>usResponse</i> is set to MBID_CANCEL, whether or not a cancel button existed within the message box.</p>
usResponse (ULONG) - returns User-response value.	
MBID_ENTER	ENTER push button was selected
MBID_OK	OK push button was selected
MBID_CANCEL	CANCEL push button was selected
MBID_ABORT	ABORT push button was selected
MBID_RETRY	RETRY push button was selected
MBID_IGNORE	IGNORE push button was selected
MBID_YES	YES push button was selected
MBID_NO	NO push button was selected
MBID_ERROR	Function not successful; an error occurred.

WinMessageBox - Remarks

The message box consists of a message and a simple dialog with the user.

This function behaves in a similar way to [WinDlgBox](#), and the remarks concerning modality which are documented under that call, and also under the [WinLoadDlg](#) and [WinProcessDlg](#) functions, also apply here.

This function should not be used while pointing device capture is set (see [WinSetCapture](#)).

If the keyboard is used to cycle from one window to the next, the message box and its parent window are considered to be next to each other in the sequence.

If a message box is created as part of the processing of a dialog window, where the dialog window has not been dismissed, the dialog window should be made the owner of the message box window.

If a system modal message box is created to indicate to the user that the system is running out of memory, the strings passed into this call must not be taken from a resource file, as an attempt to load the resource file could fail because of the lack of memory. However, such a message box can safely use the hand icon because this icon is always memory-resident.

The size of the message box is determined as follows:

- The minimum width of a message box is enough to display 40 characters of average width.
- The minimum height of a message box is enough to display 2 lines.
- The text of a message box is word-wrapped by default. If more than two lines are required to display the text, the height of the message box is increased up to a maximum of two thirds of the screen height. The height of a message box can never exceed this value.
- If necessary, the width of a message box is increased to allow room to display the title.

Text is wrapped at word boundaries (spaces). If a word is too big to fit on one line, the start of the word is not wrapped to the next line, but stays adjacent to the text it follows, and the word is split at the box boundary.

The message box is centered on the screen.

If a message box window has a CANCEL button, the MBID_CANCEL value is returned if either the Escape key is pressed or the Cancel button is selected. If the message box window has no CANCEL button, pressing the Escape key has no effect.

Note: If a dialog box or a message box is up for a window, and the parent or owner of that window is destroyed, the code following the WinDlgBox or WinMessageBox call is executed even though the parent/owner window no longer exists. This can result in accessing data that no longer exists; especially data referenced in the window words. Therefore, it is extremely important to determine the state of your child-window procedure after this function returns. The most straightforward method for doing this is to call WinQueryWindowPtr to get a pointer to the window words. If the returned pointer is NULL, then you should exit immediately. Should this be the case, the bottom-up rule (that is, the child window gets WM_DESTROY messages first, then the parent window) still applies, and it becomes the child window procedure's responsibility to exit gracefully.

WinMessageBox - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

PMERR_INVALID_FLAG (0x1019)
An invalid bit was set for a parameter. Use constants defined by PM for options, and do not set any reserved bits.

WinMessageBox - Example Code

This example shows a typical use of the WinMessageBox function when debugging an application. The C run-time function sprintf is used to format the body of the message. In this case, it converts the coordinates of the mouse pointer (retrieved with the WinQueryPointerPos function) into a string. The string is then displayed by calling WinMessageBox.

```
#define INCL_WINDIALOGS          /* Window Dialog Mgr Functions */
#define INCL_WINPOINTERS        /* Window Pointer Functions */
#include <os2.h>

CHAR szMsg[100];                /* message */
POINTL ptl;                     /* message data */
HWND hwndClient;                /* client window handle */

WinQueryPointerPos(HWND_DESKTOP, &ptl);
sprintf(szMsg, "x = %ld y = %ld", ptl.x, ptl.y);
WinMessageBox(HWND_DESKTOP,
    hwndClient,                  /* client-window handle */
    szMsg,                       /* body of the message */
    "Debugging information",     /* title of the message */
    0,                           /* message box id */
    MB_NOICON | MB_OK);          /* icon and button flags */
```

WinMessageBox2

WinMessageBox2 - Syntax

This function creates a message-box window that can be used to display error messages and ask questions.

```
#define INCL_WINDIALOGS /* Or use INCL_WIN, INCL_GPI, INCL_WINWINDOWMGR, */
#include <os2.h>

HWND hwndParent; /* Parent-window handle of the message-box window to be created. */
HWND hwndOwner; /* Requested owner-window handle of the message-box window to be created. */
PSZ pszText; /* Message-box window message. */
```

```

PSZ      pszTitle;      /* Message-box window title. */
ULONG    ulWindow;      /* Message-box window identity. */
PMB2INFO pmb2info;      /* Input structure for message-box window. */
ULONG    ulButtonId;    /* Id of the button that was clicked, or MBID_ERROR. */

ulButtonId = WinMessageBox2(hwndParent, hwndOwner,
    pszText, pszTitle, ulWindow,
    pmb2info);

```

WinMessageBox2 Parameter - hwndParent

hwndParent ([HWND](#)) - input
Parent-window handle of the message-box window to be created.

HWND-DESKTOP
The message box is to be main window.

Other
Parent-window handle.

WinMessageBox2 Parameter - hwndOwner

hwndOwner ([HWND](#)) - input
Requested owner-window handle of the message-box window to be created.

The actual owner window is calculated using the algorithm specified in the description of the [WinLoadDlg](#) function.

WinMessageBox2 Parameter - pszText

pszText ([PSZ](#)) - input
Message-box window message.

The text of the message to be displayed within the message-box window. If multiple lines are required, carriage-return characters must be inserted into the text at appropriate points.

WinMessageBox2 Parameter - pszTitle

pszTitle ([PSZ](#)) - input
Message-box window title.

The text for the title should not be longer than 40 characters. If text longer than this is supplied, text centering is still performed, even though the beginning and end of the string are not visible.

A value if NULL indicates that the text "Error" is to be displayed as the title of the message-box window.

WinMessageBox2 Parameter - ulWindow

ulWindow ([ULONG](#)) - input
Message-box window identity.

This value is passed to the HK_HELP hook if the [WM_HELP](#) message is received by the message-box window.

WinMessageBox2 Parameter - pmb2info

pmb2info ([PMB2INFO](#)) - input
Input structure for message-box window.

WinMessageBox2 Return Value - ulButtonId

ulButtonId ([ULONG](#)) - returns
Id of the button that was clicked, or MBID_ERROR.

WinMessageBox2 - Parameters

hwndParent ([HWND](#)) - input
Parent-window handle of the message-box window to be created.

HWND-DESKTOP
The message box is to be main window.
Other
Parent-window handle.

hwndOwner ([HWND](#)) - input
Requested owner-window handle of the message-box window to be created.

The actual owner window is calculated using the algorithm specified in the description of the [WinLoadDlg](#) function.

pszText ([PSZ](#)) - input
Message-box window message.

The text of the message to be displayed within the message-box window. If multiple lines are required, carriage-return characters must be inserted into the text at appropriate points.

pszTitle ([PSZ](#)) - input
Message-box window title.

The text for the title should not be longer than 40 characters. If text longer than this is supplied, text centering is still performed, even though the beginning and end of the string are not visible.

ulWindow (**ULONG**) - input
Message-box window identity.

pmb2info (PMB2INFO) - input
Input structure for mesage-box window.

WinMoveObject

WinMoveObject - Syntax

This function is specific to OS/2 Version 3.0 or higher.

This function moves an object from its existing location to a specified new destination.

```
#define INCL_WINWORKPLACE
#include <os2.h>

HOBJECT    hObjectofObject; /* Handle of the Workplace Shell object being moved. */
HOBJECT    hObjectofDest;  /* Handle of the destination folder into which hObjectofObject is to be moved. */
ULONG      ulReserved;     /* Reserved value; must be 0. */
HOBJECT    rc;             /* Handle of the source object being moved. */

rc = WinMoveObject(hObjectofObject, hObjectofDest,
    ulReserved);
```

WinMoveObject Parameter - hObjectofObject

hObjectofObject (**HOBJECT**) - input
Handle of the Workplace Shell object being moved.

WinMoveObject Parameter - hObjectofDest

hObjectofDest (**HOBJECT**) - input
Handle of the destination folder into which *hObjectofObject* is to be moved.

WinMoveObject Parameter - ulReserved

ulReserved (**ULONG**) - input
Reserved value; must be 0.

WinMoveObject Return Value - rc

rc (**HOBJECT**) - returns
Handle of the source object being moved.

A return value of NULLHANDLE indicates that either *hObjectofDest* is NULLHANDLE or an object with the same name as *hObjectofObject* exists in the destination folder.

WinMoveObject - Parameters

hObjectofObject ([HOBJECT](#)) - input

Handle of the Workplace Shell object being moved.

hObjectofDest ([HOBJECT](#)) - input

Handle of the destination folder into which *hObjectofObject* is to be moved.

ulReserved ([ULONG](#)) - input

Reserved value; must be 0.

rc ([HOBJECT](#)) - returns

Handle of the source object being moved.

A return value of NULLHANDLE indicates that either *hObjectofDest* is NULLHANDLE or an object with the same name as *hObjectofObject* exists in the destination folder.

WinMoveObject - Remarks

Using [HOBJECT](#) for .INI files or files in which an application uses a rename/save/delete sequence is not supported. Its REXX counterpart is SysMoveObject.

WinMoveObject - Errors

Possible returns from [WinGetLastError](#)

WPERR_INVALID_FLAGS (0x1719)

An invalid flag was specified.

WinMultWindowFromIDs

WinMultWindowFromIDs - Syntax

This function finds the handles of child windows that belong to a specified window and have window identities within a specified range.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>
```

```
HWND    hwndParent; /* Parent-window handle. */
HWND    prghwnd; /* Window handles. */
ULONG    idFirst; /* First window identity value in the range (inclusive). */
ULONG    idLast; /* Last window identity value in the range (inclusive). */
LONG     lWindows; /* Number of window handles returned. */

lWindows = WinMultWindowFromIDs(hwndParent,
                                prghwnd, idFirst, idLast);
```

WinMultWindowFromIDs Parameter - hwndParent

hwndParent (**HWND**) - input
Parent-window handle.

WinMultWindowFromIDs Parameter - prghwnd

prghwnd (**HWND**) - output
Window handles.

Array of window handles. The array must contain (*idLast* - *idFirst* + 1) elements. The handle of a window, whose identity is *WID* (in the range *idFirst* to *idLast*), has a zero-based index in the array of (*WID* - *idFirst*). If there is no window for a window identity within the range, the corresponding element in the array is `NULLHANDLE`.

WinMultWindowFromIDs Parameter - idFirst

idFirst (**ULONG**) - input
First window identity value in the range (inclusive).

It must be greater or equal to 0 and less or equal to 0xFFFF.

WinMultWindowFromIDs Parameter - idLast

idLast (**ULONG**) - input
Last window identity value in the range (inclusive).

It must be greater or equal to 0 and less or equal to 0xFFFF.

WinMultWindowFromIDs Return Value - lWindows

IWindows ([LONG](#)) - returns
Number of window handles returned.

0	No window handles returned
Other	Number of window handles returned.

WinMultWindowFromIDs - Parameters

hwndParent ([HWND](#)) - input
Parent-window handle.

prghwnd ([PHWND](#)) - output
Window handles.

Array of window handles. The array must contain (*idLast* - *idFirst* + 1) elements. The handle of a window, whose identity is WID (in the range *idFirst* to *idLast*), has a zero-based index in the array of (WID - *idFirst*). If there is no window for a window identity within the range, the corresponding element in the array is NULLHANDLE.

idFirst ([ULONG](#)) - input
First window identity value in the range (inclusive).

It must be greater or equal to 0 and less or equal to 0xFFFF.

idLast ([ULONG](#)) - input
Last window identity value in the range (inclusive).

It must be greater or equal to 0 and less or equal to 0xFFFF.

IWindows ([LONG](#)) - returns
Number of window handles returned.

0	No window handles returned
Other	Number of window handles returned.

WinMultWindowFromIDs - Remarks

This function can be used to enumerate all the items in a dialog group, or to enumerate all the frame controls of a standard window. This function is faster than individual calls to the [WinWindowFromID](#) function.

WinMultWindowFromIDs - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinMultWindowFromIDs - Example Code

This example finds the handles of all frame controls of a specified window via the WinMultWindowFromIDs call. The handles are returned in an array of window handles, and after the call completes, the handle for the minmax control window is assigned to a variable if a handle for it was found (i.e. handle not equal to NULLHANDLE).

```
#define INCL_WINWINDOWMGR      /* Window Manager Functions */
#define INCL_WINFRAMEMGR      /* Window Frame Functions */
#include <os2.h>

HWND  hwndParent;           /* parent window */
HWND  ahwnd[FID_CLIENT-FID_SYSMENU]; /* window handle array */
HWND  hwndMinMax;          /* minmax control window handle */
LONG  lHandles;             /* number of handles returned */

/* get all control handles between and including system menu and
   client windows */
lHandles = WinMultWindowFromIDs(hwndParent, ahwnd, FID_SYSMENU,
                                FID_CLIENT);

/* if any handles returned and the handle for the minmax control is
   not null, assign a variable to the minmax handle */
if (lHandles > 0 && ahwnd[FID_MINMAX - FID_SYSMENU] != NULLHANDLE)
    hwndMinMax = ahwnd[FID_MINMAX - FID_SYSMENU];
```

WinNextChar

WinNextChar - Syntax

This function moves to the next character in a string.

```
#define INCL_WINCOUNTRY /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
ULONG    ulCodepage;    /* Code page. */
ULONG    ulCountry;     /* Reserved value, must be 0. */
PSZ      pszCurrentChar; /* Current character in a null-terminated string. */
PSZ      pszNextChar;   /* Pointer to the next character in the null-terminated string. */

pszNextChar = WinNextChar(hab, ulCodepage,
                          ulCountry, pszCurrentChar);
```

WinNextChar Parameter - hab

hab (**HAB**) - input
Anchor-block handle.

WinNextChar Parameter - ulCodepage

ulCodepage (**ULONG**) - input
Code page.

If a non-existent code page is specified for *ulCodepage*, the code page specified by the queue associated with the calling thread is used.

WinNextChar Parameter - ulCountry

ulCountry (**ULONG**) - input
Reserved value, must be 0.

WinNextChar Parameter - pszCurrentChar

pszCurrentChar ([PSZ](#)) - input
Current character in a null-terminated string.

WinNextChar Return Value - pszNextChar

pszNextChar ([PSZ](#)) - returns
Pointer to the next character in the null-terminated string.

When the end of the string is reached, a pointer to the null-terminating character is returned.

WinNextChar - Parameters

- hab** ([HAB](#)) - input
Anchor-block handle.
- ulCodepage** ([ULONG](#)) - input
Code page.

If a non-existent code page is specified for *ulCodepage*, the code page specified by the queue associated with the calling thread is used.
- ulCountry** ([ULONG](#)) - input
Reserved value, must be 0.
- pszCurrentChar** ([PSZ](#)) - input
Current character in a null-terminated string.
- pszNextChar** ([PSZ](#)) - returns
Pointer to the next character in the null-terminated string.

When the end of the string is reached, a pointer to the null-terminating character is returned.

WinNextChar - Remarks

This function handles DBCS strings.

The following is the list of valid code pages:

Country	Code Page
Canadian-French	863
Desktop Publishing	1004
Iceland	861
Latin 1 Multilingual	850
Latin 2 Multilingual	852
Nordic	865

Portuguese	860
Turkey	857
U.S. (IBM PC)	437

Code page 1004 is compatible with Microsoft** Windows**.

The following EBCDIC code pages, based on character set 697, are also available for output:

Country	Code Page
Austrian/German	273
Belgian	500
Brazil	037
Czechoslovakia	870
Danish/Norwegian	277

WinNextChar - Example Code

This example uses WinNextChar to traverse a string until a specified character is found, while maintaining an index to point to the character's position.

```
#define INCL_WINCOUNTRY /* Window Country Functions */
#include <os2.h>

HAB    hab; /* Anchor-block handle */
ULONG  idCodepage=437; /* Code page identity of both strings */
ULONG  idCountryCode=1; /* Country code */
char    pszString1[10]; /* First string */
char    *pszNextChar; /* Next character */
char    *pszCurrentChar; /* Current character */
ULONG  ulIndex; /* Array index */

/* Set initial values */
strcpy(pszString1, "Compare");
pszCurrentChar = pszString1;

ulIndex = 0;
do
{
    pszNextChar = WinNextChar(habMain, 437, 0, pszCurrentChar);

    /* The next line is necessary to get the next char */
    pszCurrentChar = pszNextChar;

    /* Set emergency escape route, just in case */
    ulIndex = ulIndex + 1;
    if (ulIndex >10)
        break;
} while (*pszNextChar != (char)NULL);
```

WinOffsetRect

WinOffsetRect - Syntax

This function offsets a rectangle.

```
#define INCL_WINRECTANGLES /* Or use INCL_WIN, INCL_PM, */  
#include <os2.h>  
  
HAB      hab; /* Anchor-block handle. */  
PRECTL   prcl; /* Rectangle to be offset. */  
LONG     cx; /* x-value of offset. */  
LONG     cy; /* y-value of offset. */  
BOOL     rc; /* Success indicator. */  
  
rc = WinOffsetRect(hab, prcl, cx, cy);
```

WinOffsetRect Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinOffsetRect Parameter - prcl

prcl ([PRECTL](#)) - in/out
Rectangle to be offset.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) may also be used, if supported by the language.

WinOffsetRect Parameter - cx

cx (**LONG**) - input
x-value of offset.

WinOffsetRect Parameter - cy

cy (**LONG**) - input
y-value of offset.

WinOffsetRect Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinOffsetRect - Parameters

hab (**HAB**) - input
Anchor-block handle.

prcl (**PRECTL**) - in/out
Rectangle to be offset.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type **WRECT** may also be used, if supported by the language.

cx (**LONG**) - input
x-value of offset.

cy (**LONG**) - input
y-value of offset.

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinOffsetRect - Remarks

This function offsets the coordinates of *prc* by adding the value of the *cx* parameter to both the left and right coordinates, and the value of the *cy* to both the top and bottom coordinates.

WinOffsetRect - Example Code

This example moves a rectangle in response to the movement of the mouse (WM_MOUSEMOVE); the rectangle is moved (offset) based on the distance moved by the mouse since its previous position.

```
#define INCL_WINRECTANGLES      /* Window Rectangle Functions */
#include <os2.h>

int main(void)
{
    BOOL    fSuccess;           /* success indicator */
    HAB     hab;                /* anchor-block handle */
    RECTL   prclRect1 = {0,0,100,100}; /* rectangle */
    LONG    lcx;                /* Horizontal expansion */
    LONG    lcy;                /* Vertical expansion */
    POINTL   ptlPrev;           /* previous mouse position */
    POINTL   ptlCurr;           /* current mouse position */
    MPARAM   mpl;               /* Parameter 1 (x,y) point value */

    case WM_MOUSEMOVE:
        ptlCurr.x = (LONG) SHORT1FROMMP(mpl);
        ptlCurr.y = (LONG) SHORT2FROMMP(mpl);

        /* calculate distance from previous mouse position */
        lcx = (LONG)(ptlPrev.x - ptlCurr.x);
        lcy = (LONG)(ptlPrev.y - ptlCurr.y);

        fSuccess = WinOffsetRect(hab, &prclRect1, lcx, lcy);
```

WinOpenClipbrd

WinOpenClipbrd - Syntax

This function opens the clipboard.

```
#define INCL_WINCLIPBOARD /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB    hab; /* Anchor-block handle. */
BOOL    rc; /* Success indicator. */

rc = WinOpenClipbrd(hab);
```

WinOpenClipbrd Parameter - hab

hab (**HAB**) - input
Anchor-block handle.

WinOpenClipbrd Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Clipboard successfully opened
FALSE	Error occurred.

WinOpenClipbrd - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Clipboard successfully opened
FALSE	Error occurred.

WinOpenClipbrd - Remarks

The process reading the clipboard does not become the owner of the object in it; it must not update or free the object.

This function prevents other threads and processes from examining or changing the clipboard contents.

If another thread or process already has the clipboard open, this function does not return until the clipboard is closed.

Messages can be received from other threads and processes during the processing of this function.

WinOpenObject

WinOpenObject - Syntax

This function is specific to OS/2 Version 3.0 or higher.

This function either opens a view of the given object or surfaces an existing view.

```
#define INCL_WINWORKPLACE
#include <os2.h>

HOBJECT    hObjectofObject; /* Handle to a Workplace Shell object to be opened. */
ULONG      ulView;          /* View in which to open the specified object. */
BOOL       fFlags;          /* Flags. */
BOOL       rc;              /* Success indicator. */

rc = WinOpenObject(hObjectofObject, ulView,
                   fFlags);
```

WinOpenObject Parameter - hObjectofObject

hObjectofObject ([HOBJECT](#)) - input

Handle to a Workplace Shell object to be opened.

WinOpenObject Parameter - ulView

ulView ([ULONG](#)) - input

View in which to open the specified object.

OPEN_SETTINGS

OPEN_TREE

OPEN_DEFAULT
OPEN_CONTENTS
OPEN_DETAILS

WinOpenObject Parameter - fFlags

fFlags (BOOL) - input
Flags.

TRUE	Open a view of the object which already exists and supports concurrent views, by calling wpViewObject.
FALSE	Open a view of this object by calling wpOpen.

WinOpenObject Return Value - rc

rc (BOOL) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinOpenObject - Parameters

hObjectofObject (HOBJECT) - input
Handle to a Workplace Shell object to be opened.

ulView (ULONG) - input
View in which to open the specified object.

OPEN_SETTINGS
OPEN_TREE
OPEN_DEFAULT
OPEN_CONTENTS
OPEN_DETAILS

fFlags (BOOL) - input
Flags.

TRUE

FALSE	Open a view of the object which already exists and supports concurrent views, by calling wpViewObject.
	Open a view of this object by calling wpOpen.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinOpenObject - Remarks

Using [HOBJECT](#) for .INI files or files in which an application uses a rename/save/delete sequence is not supported. Its REXX counterpart is SysOpenObject. If concurrent views is off, wpViewObject will resurface an existing object.

WinOpenWindowDC

WinOpenWindowDC - Syntax

This function opens a device context for a window.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HWND     hwnd; /* Window handle. */
HDC      hdc;  /* Device-context handle. */

hdc = WinOpenWindowDC(hwnd);
```

WinOpenWindowDC Parameter - hwnd

hwnd ([HWND](#)) - input
Window handle.

WinOpenWindowDC Return Value - hdc

hdc ([HDC](#)) - returns
Device-context handle.

WinOpenWindowDC - Parameters

hwnd ([HWND](#)) - input
Window handle.

hdc ([HDC](#)) - returns
Device-context handle.

WinOpenWindowDC - Remarks

hdc is used to associate a presentation space with the window.

Note: The window device context is automatically closed when its associated window is destroyed. It must not be closed with the [DevCloseDC](#) call.

The visible region of the device context is updated automatically as windows are rearranged.

WinOpenWindowDC - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinPeekMsg

WinPeekMsg - Syntax

This function inspects the thread's message queue and returns to the application with or without a message.

```
#define INCL_WINMESSAGEGR /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
PQMSG    pqmsg;        /* Message structure. */
HWND     hwndFilter;   /* Window filter. */
ULONG    ulFirst;      /* First message identity. */
ULONG    ulLast;       /* Last message identity. */
ULONG    flOptions;    /* Options. */
BOOL     rc;           /* Message-available indicator. */

rc = WinPeekMsg(hab, pqmsg, hwndFilter, ulFirst,
               ulLast, flOptions);
```

WinPeekMsg Parameter - hab

hab (**HAB**) - input
Anchor-block handle.

WinPeekMsg Parameter - pqmsg

pqmsg (**PQMSG**) - output
Message structure.

Note: If the function returns FALSE, the state of the QMSG structure is undefined. Applications should always check the return code before examining this structure.

WinPeekMsg Parameter - hwndFilter

hwndFilter (**HWND**) - input
Window filter.

WinPeekMsg Parameter - ulFirst

ulFirst (**ULONG**) - input
First message identity.

WinPeekMsg Parameter - ulLast

ulLast (**ULONG**) - input
Last message identity.

WinPeekMsg Parameter - flOptions

flOptions (**ULONG**) - input
Options.

If neither of the following flags is specified, the message is not removed. If both of the following flags are specified, the message is removed:

PM_REMOVE	Remove message from queue
PM_NOREMOVE	Do not remove message from queue.

WinPeekMsg Return Value - rc

rc (**BOOL**) - returns
Message-available indicator.

TRUE	Message available
FALSE	No message available.

WinPeekMsg - Parameters

hab (**HAB**) - input
Anchor-block handle.

pqmsg (**PQMSG**) - output
Message structure.

Note: If the function returns FALSE, the state of the QMSG structure is undefined. Applications should always check the return code before examining this structure.

hwndFilter (**HWND**) - input
Window filter.

ulFirst (**ULONG**) - input
First message identity.

ulLast (**ULONG**) - input
Last message identity.

flOptions (**ULONG**) - input

Options.

If neither of the following flags is specified, the message is not removed. If both of the following flags are specified, the message is removed:

PM_REMOVE	Remove message from queue
PM_NOREMOVE	Do not remove message from queue.

rc ([BOOL](#)) - returns
Message-available indicator.

TRUE	Message available
FALSE	No message available.

WinPeekMsg - Remarks

This function is identical to the [WinGetMsg](#) function, except that it does not wait for the arrival of a message. The message can be left on the queue, by using */fOptions*.

For details of *hwndFilter*, *ulFirst*, and *ulLast*, see the [WinGetMsg](#) function.

The window handle within *pqmsg* is null if the message is posted to the queue with a *hwnd* that is null.

WinPeekMsg - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

PMERR_INVALID_FLAG (0x1019)
An invalid bit was set for a parameter. Use constants defined by PM for options, and do not set any reserved bits.

WinPeekMsg - Example Code

This example uses WinPeekMsg to count the total number of pending messages for the window corresponding to hwndFilter.

```
#define INCL_WINMESSAGEGR      /* Window Message Functions */
#define INCL_WINWINDOWMGR     /* Window Manager Functions */
#include <os2.h>

HAB      hab;           /* anchor-block handle */
QMSG     qmsg;          /* message */
HWND     hwndFilter;    /* message queue filter */
ULONG    flOptions;     /* peek options */
ULONG    ulMsgCount=0;  /* message count */

/* don't remove messages */
flOptions = PM_NOREMOVE;

/* count number of messages for filter window */
while (WinPeekMsg (hab, &qmsg, hwndFilter, 0, 0, flOptions))
    ulMsgCount++;
```

WinPopupMenu

WinPopupMenu - Syntax

This function causes a pop-up menu to be presented.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwndParent; /* Parent-window handle. */
HWND    hwndOwner;  /* Owner-window handle. */
HWND    hwndMenu;   /* Pop-up menu-window handle. */
LONG    x;          /* x-coordinate of the pop-up menu position. */
LONG    y;          /* y-coordinate of the pop-up menu position. */
LONG    idItem;     /* Item identity. */
ULONG   fs;         /* Options. */
BOOL    rc;         /* Pop-up menu invoked indicator. */

rc = WinPopupMenu(hwndParent, hwndOwner, hwndMenu,
    x, y, idItem, fs);
```

WinPopupMenu Parameter - hwndParent

hwndParent ([HWND](#)) - input
Parent-window handle.

WinPopupMenu Parameter - hwndOwner

hwndOwner ([HWND](#)) - input
Owner-window handle.

The owner window receives all the notification messages generated by the pop-up menu.

WinPopupMenu Parameter - hwndMenu

hwndMenu ([HWND](#)) - input
Pop-up menu-window handle.

The pop-up menu must have been created, by use of either the [WinCreateMenu](#) or [WinLoadMenu](#) functions.

WinPopupMenu Parameter - x

x ([LONG](#)) - input
x-coordinate of the pop-up menu position.

The value is in window coordinates relative to the origin of the parent window.

The x-coordinate of the origin of the pop-up menu can be affected, if either of the [PU_POSITIONONITEM](#) or [PU_HCONSTRAIN](#)

values of the *fs* parameter is also set.

WinPopupMenu Parameter - y

y (**LONG**) - input
y-coordinate of the pop-up menu position.

The value is in window coordinates relative to the origin of the parent window.

The y-coordinate of the origin of the pop-up menu can be affected, if either of the PU_POSITIONONITEM or PU_VCONSTRAIN values of the *fs* parameter is also set.

WinPopupMenu Parameter - idItem

idItem (**LONG**) - input
Item identity.

This is used if either the PU_POSITIONONITEM or PU_SELECTITEM of the *fs* parameter is also set. It must be greater or equal to 0 and less or equal to 0xFFFF.

WinPopupMenu Parameter - fs

fs (**ULONG**) - input
Options.

Position

Pop-up menu position.

PU_POSITIONONITEM

Position the pop-up menu so that the item identified by the *idItem* parameter of the top-level menu specified by the *hwndMenu* parameter lies directly under the *x* \ *y* coordinates.

The position of the pop-up menu can be affected, if either the PU_HCONSTRAIN or or PU_VCONSTRAIN values of the *fs* parameter is also set.

This value also causes the pop-up menu item identified by the *idItem* to be selected.

Restrain

Pop-up menu position constraints.

These options allow the application to ensure that the pop-up menu is visible on the desktop.

PU_HCONSTRAIN

Constrain the pop-up menu so that its width is wholly visible on the desktop.

If necessary the position of the pop-up menu will be adjusted so that its left edge is coincident with the left edge of the desktop or that its right edge is coincident with the right edge of the desktop.

PU_VCONSTRAIN

Constrain the pop-up menu so that its height is wholly visible on the desktop.

If necessary the position of the pop-up menu will be adjusted so that its top edge is coincident with the top edge of the desktop or that its bottom edge is coincident with the bottom edge of the desktop.

InitialState

Initial input state of the pop-up menu.

This allows the user interaction which caused the application to summon the pop-up menu to be carried through as the initial user interaction with the pop-up menu.

For example, this permits the application to support the user interface in which mouse button 1 can be depressed to cause the pop-up menu to be presented and held down while moving the mouse over the menu in order to select another menu item and then released to dismiss the menu.

Only one of the following values can be selected:

PU_MOUSEBUTTON1DOWN

The pop-up menu is initialized with mouse button 1 depressed.

PU_MOUSEBUTTON2DOWN

The pop-up menu is initialized with mouse button 2 depressed.

PU_MOUSEBUTTON3DOWN

The pop-up menu is initialized with mouse button 3 depressed.

PU_NONE

The pop-up menu is to be presented uninfluenced by the user interaction which caused it to be summoned.

This is the default value.

Select

Item selection.

PU_SELECTITEM

The item identified by *idItem* is to be selected. This is only valid if PU_NONE is set in the *InitialState* parameter.

If the identified item is in a submenu of the pop-up menu, then all the previous submenus in the menu hierarchy are presented with the correct path to the identified item.

Usage

Input device usage.

The window procedure controlling the pop-up menu must be informed of which input devices are available for interaction with the pop-up menu.

These options are independent to those of the *InitialState* parameter. Therefore, if an application indicates in the *InitialState* parameter that the pop-up menu is to be initialized with a particular user interaction, then the mechanism which permits that user interaction would usually be specified in this parameter. In this way the user's expectation, that once a device has been employed for the manipulation of the pop-up menu then that device can continue to be used for that purpose, is fulfilled.

It is valid to specify a user interaction as an initialization of the pop-up menu by an input mechanism which is not identified as available for interaction with the pop-up menu. This implies that the user cannot necessarily complete the interaction with the pop-up menu with that input mechanism.

For example, if a pop-up menu is initialized with a mouse button depressed but that mouse button is not identified as available for manipulating the pop-up menu, then that mouse button can manipulate the pop-up menu until it is released. Assuming that the pop-up menu is not dismissed when that mouse button is released, then the mouse button cannot be used for further interaction with the pop-up menu, since it is not identified as available for that use.

The following list shows the input device valid for interaction with the pop-up menu with each option:

PU_KEYBOARD

The keyboard.

PU_MOUSEBUTTON1

Mouse button 1.

PU_MOUSEBUTTON2

Mouse button 2.

PU_MOUSEBUTTON3

Mouse button 3.

WinPopupMenu Return Value - rc

rc (**BOOL**) - returns

Pop-up menu invoked indicator.

This function returns as soon as the pop-up menu has been invoked, which might be before the user has completed interacting with the pop-up menu.

TRUE

Pop-up menu successfully invoked

FALSE

Pop-up menu not successfully invoked.

WinPopupMenu - Parameters

hwndParent (**HWND**) - input

Parent-window handle.

hwndOwner (**HWND**) - input

Owner-window handle.

The owner window receives all the notification messages generated by the pop-up menu.

hwndMenu (**HWND**) - input

Pop-up menu-window handle.

The pop-up menu must have been created, by use of either the [WinCreateMenu](#) or [WinLoadMenu](#) functions.

x (**LONG**) - input

x-coordinate of the pop-up menu position.

The value is in window coordinates relative to the origin of the parent window.

The x-coordinate of the origin of the pop-up menu can be affected, if either of the `PU_POSITIONONITEM` or `PU_HCONSTRAIN` values of the `/s` parameter is also set.

y (**LONG**) - input

y-coordinate of the pop-up menu position.

The value is in window coordinates relative to the origin of the parent window.

The y-coordinate of the origin of the pop-up menu can be affected, if either of the `PU_POSITIONONITEM` or `PU_VCONSTRAIN` values of the `/s` parameter is also set.

idItem (**LONG**) - input

Item identity.

This is used if either the `PU_POSITIONONITEM` or `PU_SELECTITEM` of the `/s` parameter is also set. It must be greater or equal to 0 and less or equal to 0xFFFF.

fs (**ULONG**) - input

Options.

Position

Pop-up menu position.

PU_POSITIONONITEM

Position the pop-up menu so that the item identified by the *idItem* parameter of the top-level menu specified by the *hwndMenu* parameter lies directly under the $x \setminus y$ coordinates.

The position of the pop-up menu can be affected, if either the PU_HCONSTRAIN or or PU_VCONSTRAIN values of the *fs* parameter is also set.

This value also causes the pop-up menu item identified by the *idItem* to be selected.

Restrain

Pop-up menu position constraints.

These options allow the application to ensure that the pop-up menu is visible on the desktop.

PU_HCONSTRAIN

Constrain the pop-up menu so that its width is wholly visible on the desktop.

If necessary the position of the pop-up menu will be adjusted so that its left edge is coincident with the left edge of the desktop or that its right edge is coincident with the right edge of the desktop.

PU_VCONSTRAIN

Constrain the pop-up menu so that its height is wholly visible on the desktop.

If necessary the position of the pop-up menu will be adjusted so that its top edge is coincident with the top edge of the desktop or that its bottom edge is coincident with the bottom edge of the desktop.

InitialState

Initial input state of the pop-up menu.

This allows the user interaction which caused the application to summon the pop-up menu to be carried through as the initial user interaction with the pop-up menu.

For example, this permits the application to support the user interface in which mouse button 1 can be depressed to cause the pop-up menu to be presented and held down while moving the mouse over the menu in order to select another menu item and then released to dismiss the menu.

Only one of the following values can be selected:

PU_MOUSEBUTTON1DOWN

The pop-up menu is initialized with mouse button 1 depressed.

PU_MOUSEBUTTON2DOWN

The pop-up menu is initialized with mouse button 2 depressed.

PU_MOUSEBUTTON3DOWN

The pop-up menu is initialized with mouse button 3 depressed.

PU_NONE

The pop-up menu is to be presented uninfluenced by the user interaction which caused it to be summoned.

This is the default value.

Select

Item selection.

PU_SELECTITEM

The item identified by *idItem* is to be selected. This is only valid if PU_NONE is set in the *InitialState* parameter.

If the identified item is in a submenu of the pop-up menu, then all the previous submenus in the menu hierarchy are presented with the correct path to the identified item.

Usage

Input device usage.

The window procedure controlling the pop-up menu must be informed of which input devices are available for interaction with the pop-up menu.

These options are independent to those of the *InitialState* parameter. Therefore, if an application indicates in the *InitialState* parameter that the pop-up menu is to be initialized with a particular user interaction, then the

mechanism which permits that user interaction would usually be specified in this parameter. In this way the user's expectation, that once a device has been employed for the manipulation of the pop-up menu then that device can continue to be used for that purpose, is fulfilled.

It is valid to specify a user interaction as an initialization of the pop-up menu by an input mechanism which is not identified as available for interaction with the pop-up menu. This implies that the user cannot necessarily complete the interaction with the pop-up menu with that input mechanism.

For example, if a pop-up menu is initialized with a mouse button depressed but that mouse button is not identified as available for manipulating the pop-up menu, then that mouse button can manipulate the pop-up menu until it is released. Assuming that the pop-up menu is not dismissed when that mouse button is released, then the mouse button cannot be used for further interaction with the pop-up menu, since it is not identified as available for that use.

The following list shows the input device valid for interaction with the pop-up menu with each option:

PU_KEYBOARD	The keyboard.
PU_MOUSEBUTTON1	Mouse button 1.
PU_MOUSEBUTTON2	Mouse button 2.
PU_MOUSEBUTTON3	Mouse button 3.

rc ([BOOL](#)) - returns

Pop-up menu invoked indicator.

This function returns as soon as the pop-up menu has been invoked, which might be before the user has completed interacting with the pop-up menu.

TRUE

Pop-up menu successfully invoked

FALSE

Pop-up menu not successfully invoked.

WinPopupMenu - Remarks

A pop-up menu is the unanchored equivalent of a pull-down menu, that is it can be positioned anywhere rather than being associated with an action bar. Typically, pop-up menus are related to specific objects, such as an icon, or with a particular area of the application's presentation space.

Once invoked, a pop-up menu behaves in exactly the same way as a pull-down menu.

WinPopupMenu - Example Code

This example presents a pop-up menu (loaded from RES.DLL by WinLoadMenu) with the following characteristics: located at (0,50);

initialized with mouse button 1 depressed; allowing keyboard and mouse button 1 interaction.

```
#define INCL_WINWINDOWMGR      /* Window Manager Functions */
#define INCL_WINMENUS         /* Window Menu Functions */
#include <os2.h>

HWND      hwndMenu;           /* menu window */
HWND      hwndOwner;          /* owner window */
HMODULE    hmodDLL;           /* resource handle */
ULONG      idMenuid;          /* resource menu id */
BOOL       fSuccess;          /* success indicator */
HWND      hwndParent;         /* parent window */
ULONG      flOptions;         /* pop-up menu options */

if (DosQueryModuleHandle("RES.DLL",&hmodDLL))
    hwndMenu = WinLoadMenu(hwndOwner, hmodDLL, idMenuid);

flOptions = PU_MOUSEBUTTON1DOWN | PU_KEYBOARD | PU_MOUSEBUTTON1;
fSuccess = WinPopupMenu(hwndParent, hwndOwner, hwndMenu, 0, 50,
                        0, flOptions);
```

WinPostMsg

WinPostMsg - Syntax

This function posts a message to the message queue associated with the window defined by *hwnd*.

```
#define INCL_WINMESSAGEGR /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HWND      hwnd;           /* Window handle. */
ULONG      ulMsgid;       /* Message identity. */
MPARAM      mpParam1;     /* Parameter 1. */
MPARAM      mpParam2;     /* Parameter 2. */
BOOL       rc;            /* Message-posted indicator. */

rc = WinPostMsg(hwnd, ulMsgid, mpParam1, mpParam2);
```

WinPostMsg Parameter - hwnd

hwnd (HWND) - input	Window handle.
NULL	The message is posted into the queue associated with the current thread. When the message is received by using the WinGetMsg or WinPeekMsg functions, the parameter of the QMSG structure is NULL.
Other	Window handle.

WinPostMsg Parameter - ulMsgid

ulMsgid (ULONG) - input	Message identity.
--	-------------------

WinPostMsg Parameter - mpParam1

mpParam1 (MPARAM) - input	Parameter 1.
--	--------------

WinPostMsg Parameter - mpParam2

mpParam2 (MPARAM) - input	Parameter 2.
--	--------------

WinPostMsg Return Value - rc

rc (BOOL) - returns	Message-posted indicator.
TRUE	Message successfully posted
FALSE	Message could not be posted; for example, because the message queue was full.

WinPostMsg - Parameters

hwnd ([HWND](#)) - input
Window handle.

NULL

The message is posted into the queue associated with the current thread. When the message is received by using the [WinGetMsg](#) or [WinPeekMsg](#) functions, the parameter of the [QMSG](#) structure is NULL.

Other

Window handle.

ulMsgid ([ULONG](#)) - input
Message identity.

mpParam1 ([MPARAM](#)) - input
Parameter 1.

mpParam2 ([MPARAM](#)) - input
Parameter 2.

rc ([BOOL](#)) - returns
Message-posted indicator.

TRUE

Message successfully posted

FALSE

Message could not be posted; for example, because the message queue was full.

WinPostMsg - Remarks

The message contains *hwnd*, *ulMsgid*, *mpParam1*, *mpParam2*, and the time and pointer position when this function is called.

WinPostMsg returns immediately, while [WinSendMsg](#) waits for the receiver to return.

A thread which does not have a message queue can still call WinPostMsg but cannot call [WinSendMsg](#).

WinPostMsg - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinPostQueueMsg

WinPostQueueMsg - Syntax

This function posts a message to a message queue.

```
#define INCL_WINMESSAGEGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HMQ      hmq; /* Message-queue handle. */
ULONG    msg; /* Message identifier. */
MPARAM    mp1; /* Parameter 1. */
MPARAM    mp2; /* Parameter 2. */
BOOL      rc; /* Success indicator. */

rc = WinPostQueueMsg(hmq, msg, mp1, mp2);
```

WinPostQueueMsg Parameter - hmq

hmq ([HMQ](#)) - input
Message-queue handle.

WinPostQueueMsg Parameter - msg

msg ([ULONG](#)) - input
Message identifier.

WinPostQueueMsg Parameter - mp1

mp1 ([MPARAM](#)) - input
Parameter 1.

WinPostQueueMsg Parameter - mp2

mp2 ([MPARAM](#)) - input
Parameter 2.

WinPostQueueMsg Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred, or the queue was full.

WinPostQueueMsg - Parameters

hmq ([HMQ](#)) - input
Message-queue handle.

msg ([ULONG](#)) - input
Message identifier.

mp1 ([MPARAM](#)) - input
Parameter 1.

mp2 ([MPARAM](#)) - input
Parameter 2.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred, or the queue was full.

WinPostQueueMsg - Remarks

This function can be used to post messages to any queue in the system.

It constructs a [QMSG](#) structure by setting its parameters from the corresponding parameters of this function, and by deriving its parameters from the system time and pointer position when this function was called. The [QMSG](#) structure is then placed on the specified queue.

WinPostQueueMsg - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HMQ (0x1002)
An invalid message-queue handle was specified.

WinPrevChar

WinPrevChar - Syntax

This function moves to the previous character in a string.

```
#define INCL_WINCOUNTRY /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;           /* Anchor-block handle. */
ULONG    ulCodepage;    /* Code page. */
ULONG    ulCountry;     /* Reserved value, must be 0. */
PSZ      pszStart;      /* Character string that contains pszCurrentChar. */
PSZ      pszCurrentChar; /* Current character. */
PSZ      pszPrevChar;   /* Previous character. */

pszPrevChar = WinPrevChar(hab, ulCodepage,
                          ulCountry, pszStart, pszCurrentChar);
```

WinPrevChar Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinPrevChar Parameter - ulCodepage

ulCodepage ([ULONG](#)) - input
Code page.

If a non-existent code page is specified for *ulCodepage*, the code page specified by the queue associated with the calling thread is used.

WinPrevChar Parameter - ulCountry

ulCountry ([ULONG](#)) - input
Reserved value, must be 0.

WinPrevChar Parameter - pszStart

pszStart ([PSZ](#)) - input
Character string that contains *pszCurrentChar*.

WinPrevChar Parameter - pszCurrentChar

pszCurrentChar ([PSZ](#)) - input
Current character.

WinPrevChar Return Value - pszPrevChar

pszPrevChar ([PSZ](#)) - returns
Previous character.

The previous character, or the first character if *pszCurrentChar* is the first character of *pszStart*.

WinPrevChar - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

ulCodepage ([ULONG](#)) - input
Code page.

If a non-existent code page is specified for *ulCodepage*, the code page specified by the queue associated with the calling thread is used.

ulCountry ([ULONG](#)) - input
Reserved value, must be 0.

pszStart ([PSZ](#)) - input

Character string that contains *pszCurrentChar*.

pszCurrentChar (PSZ) - input
Current character.

pszPrevChar (PSZ) - returns
Previous character.

The previous character, or the first character if *pszCurrentChar* is the first character of *pszStart*.

WinPrevChar - Remarks

This function handles DBCS strings.

Code pages 274 (Belgian) and 282 (Portuguese) can be used to provide access to old data. The following is the list of valid country codes:

Country	Code
Arabic	785
Australian	61
Belgian	32
Canadian-French	2
Danish	45
Finnish	358
French	33
German	49
Hebrew	972
Italian	39
Japanese	81
Korean	82

```

COUNTRYCODE Country;
COUNTRYINFO CtryBuffer;

Country.country = CURRENT_COUNTRY;

DosQueryCp((ULONG)2,
            &CodePage,           /* Get code page identifier */
            &DataLength);

/* First WORD contains the codepage */
Country.codepage = (ULONG)HIUSHORT(CodePage);

/* Get the corresponding country code */
DosQueryCtryInfo(sizeof(CtryBuffer), /* Length of data area */
                  &Country,          /* Input data structure */
                  &CtryBuffer,       /* Data area to be filled */
                  &DataLength);      /* Length of data */

/* A pointer should be returned to character "D" in the string */
ptoD = WinPrevChar(hab,
                  (ULONG)CodePage,
                  (ULONG)CtryBuffer.country,
                  (PSZ)string,
                  ptoE); /* Pointer to character "E" */

WinProcessDlg

WinProcessDlg - Syntax

This function dispatches messages while a modal dialog window is displayed.

```

#define INCL_WINDIALOGS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwndDlg; /* Dialog-window handle. */
ULONG    ulReply; /* Reply value. */

ulReply = WinProcessDlg(hwndDlg);

```

WinProcessDlg Parameter - hwndDlg

hwndDlg ([HWND](#)) - input
Dialog-window handle.

WinProcessDlg Return Value - ulReply

ulReply ([ULONG](#)) - returns
Reply value.

Value established by the [WinDismissDlg](#) function.

WinProcessDlg - Parameters

hwndDlg ([HWND](#)) - input
Dialog-window handle.

ulReply ([ULONG](#)) - returns
Reply value.

Value established by the [WinDismissDlg](#) function.

WinProcessDlg - Remarks

If the dialog has an owner window, that window is disabled. This means that all user input to the owner, and its descendants, is prevented.

This function then dispatches messages from the queue to the appropriate window or dialog procedure until the dialog is dismissed by [WinDismissDlg](#). This is usually done by the dialog procedure on receipt of an appropriate message, but also occurs if the dialog procedure passes a [WM_COMMAND](#) message to [WinDefDlgProc](#) or if the [WM_QUIT](#) message is encountered before the dialog window is dismissed. In this latter case, [WinProcessDlg](#) itself issues [WinDismissDlg](#), and posts the [WM_QUIT](#) message back to the queue so that the application main loop terminates in the normal way.

This function shows the window, if it is hidden, when the queue is empty. It is therefore possible for the experienced user to type ahead and cause the dialog to be dismissed before it becomes visible.

If the dialog window needs to be processed through [WinProcessDlg](#), after being dismissed, the [FF_DLGDISMISSED](#) flag must be reset.

[WinDismissDlg](#) hides the dialog window without destroying it, and also re-enables any window that was disabled by this function.

This function does not return until a [WinDismissDlg](#) call is issued in one of the ways listed above. This is true even if the application main window has not been disabled, for example because the dialog window has no owner. In this case, the dialog will appear to the user to be modeless; the user will continue to be able to interact with the application, and possibly create multiple instances of the dialog. In such circumstances the operating system calls the application main window procedure recursively before [WinProcessDlg](#) returns.

It is not possible to temporarily disable more than one window using this function; a dialog window can have at most one owner. If an application has more than one main window which should be disabled while the modal dialog is displayed, it can be done by setting appropriate hooks using [WinSetHook](#).

If the dialog window is a descendant of its owner, this function disables input to the dialog itself. However, this situation can only occur by explicitly changing the window hierarchy. Dialog windows are created using [WinLoadDlg](#) or [WinCreateDlg](#), which modify the owner window specified on their parameter lists.

WinProcessDlg - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinPtInRect

WinPtInRect - Syntax

This function queries whether a point lies within a rectangle.

```

#define INCL_WINRECTANGLES /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab; /* Anchor-block handle. */
PRECTL   prcl; /* Rectangle to be queried. */
PPOINTL  pptl; /* Point to be queried. */
BOOL     rc; /* Success indicator. */

rc = WinPtInRect(hab, prcl, pptl);

```

WinPtInRect Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinPtInRect Parameter - prcl

prcl ([PRECTL](#)) - input
Rectangle to be queried.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) may also be used, if supported by the language.

WinPtInRect Parameter - pptl

pptl ([PPOINTL](#)) - input
Point to be queried.

WinPtInRect Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

- | | |
|-------|---|
| TRUE | <i>pptl</i> lies within <i>prcl</i> . |
| FALSE | <i>pptl</i> does not lie within <i>prcl</i> , or an error occurred. |
-

WinPtInRect - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

prcl ([PRECTL](#)) - input
Rectangle to be queried.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) may also be used, if supported by the language.

pptl ([PPOINTL](#)) - input
Point to be queried.

rc ([BOOL](#)) - returns
Success indicator.

TRUE
FALSE

pptl lies within *prcl*.

pptl does not lie within *prcl*, or an error occurred.

WinQueryAccelTable

WinQueryAccelTable - Syntax

This function queries the window or queue accelerator table.

```

#define INCL_WINACCELERATORS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
HWND     hwndFrame;     /* Frame-window handle. */
HACCEL    haccelAccel;  /* Accelerator-table handle. */

haccelAccel = WinQueryAccelTable(hab, hwndFrame);

```

WinQueryAccelTable Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinQueryAccelTable Parameter - hwndFrame

hwndFrame ([HWND](#)) - input
Frame-window handle.

NULLHANDLE

Return queue accelerator.

Other

Return the window accelerator table, by sending the [WM_QUERYACCELTABLE](#) message to *hwndFrame*.

WinQueryAccelTable Return Value - haccelAccel

haccelAccel ([HACCEL](#)) - returns
Accelerator-table handle.

NULLHANDLE

Error occurred

Other

Accelerator-table handle.

WinQueryAccelTable - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

hwndFrame ([HWND](#)) - input
Frame-window handle.

NULLHANDLE

Return queue accelerator.

Other

Return the window accelerator table, by sending the [WM_QUERYACCELTABLE](#) message to *hwndFrame*.

haccelAccel ([HACCEL](#)) - returns
Accelerator-table handle.

NULLHANDLE

Error occurred

Other

Accelerator-table handle.

WinQueryAccelTable - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)

An invalid window handle was specified.

WinQueryActiveDesktopPathname

WinQueryActiveDesktopPathname - Syntax

This function is specific to OS/2 Version 3.0 or higher.

This function returns the directory specification of the active desktop.

```
#define INCL_WINWORKPLACE
#include <os2.h>

PSZ      pszPathName; /* Memory allocated by caller in which directory specification is written. */
ULONG    ulSize;      /* Number of bytes pointed to by pszPathName. */
BOOL     rc;          /* Success indicator. */

rc = WinQueryActiveDesktopPathname(pszPathName,
                                   ulSize);
```

WinQueryActiveDesktopPathname Parameter - pszPathName

pszPathName ([PSZ](#)) - output
Memory allocated by caller in which directory specification is written.

WinQueryActiveDesktopPathname Parameter - ulSize

ulSize ([ULONG](#)) - input
Number of bytes pointed to by *pszPathName*.

WinQueryActiveDesktopPathname Return Value - rc

rc ([BOOL](#)) - returns

Success indicator.

TRUE

Successful completion

FALSE

Error occurred.

WinQueryActiveDesktopPathname - Parameters

pszPathName ([PSZ](#)) - output

Memory allocated by caller in which directory specification is written.

ulSize ([ULONG](#)) - input

Number of bytes pointed to by *pszPathName*.

rc ([BOOL](#)) - returns

Success indicator.

TRUE

Successful completion

FALSE

Error occurred.

WinQueryActiveDesktopPathname - Remarks

This function is used to find the directory specification of the current desktop. The current desktop is not always \DESKTOP of the boot drive.

WinQueryActiveDesktopPathname - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_PARAMETER (0x1645)

An application parameter value is invalid for its converted PM type. For example: a 4-byte value outside the range -32,768 to +32,767 cannot be converted to a SHORT, and a negative number cannot be converted to a ULONG or USHORT.

WinQueryActiveDesktopPathname - Example Code

This example finds the directory specification of the current desktop.

```
#define INCL_WINWORKPLACE
#include <os2.h>

CHAR    szPath[CCHMAXPATH + 1];
BOOL    fSuccess;

fSuccess = WinQueryActiveDesktopPathname(szPath, sizeof(szPath));
if (fSuccess)
```

```

{
    /* WinQueryActiveDesktopPathname was successful */
}
else
{
    /* WinQueryActiveDesktopPathname failed */
}

```

WinQueryActiveWindow

WinQueryActiveWindow - Syntax

This function returns the active window for HWND_DESKTOP, or other parent window.

```

#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwndParent; /* Parent-window handle for which the active window is required. */
HWND    hwndActive; /* Active-window handle. */

hwndActive = WinQueryActiveWindow(hwndParent);

```

WinQueryActiveWindow Parameter - hwndParent

hwndParent (**HWND**) - input

Parent-window handle for which the active window is required.

HWND_DESKTOP

The desktop-window handle that causes this function to return the top-level frame window.

Other

Specified parent-window handle.

WinQueryActiveWindow Return Value - hwndActive

hwndActive ([HWND](#)) - returns
Active-window handle.

NULLHANDLE
No window is active
Other
Active-window handle.

WinQueryActiveWindow - Parameters

hwndParent ([HWND](#)) - input
Parent-window handle for which the active window is required.

HWND_DESKTOP
The desktop-window handle that causes this function to return the top-level frame window.
Other
Specified parent-window handle.

hwndActive ([HWND](#)) - returns
Active-window handle.

NULLHANDLE
No window is active
Other
Active-window handle.

WinQueryActiveWindow - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

This function returns the anchor block handle of the caller.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HWND    hwnd; /* Window handle. */
HAB     hab;  /* Anchor block handle. */

hab = WinQueryAnchorBlock(hwnd);
```

WinQueryAnchorBlock Parameter - hwnd

hwnd ([HWND](#)) - input
Window handle.

WinQueryAnchorBlock Return Value - hab

hab ([HAB](#)) - returns
Anchor block handle.

NULLHANDLE

Invalid *hwnd* parameter

Other

Anchor block handle.

WinQueryAnchorBlock - Parameters

hwnd ([HWND](#)) - input
Window handle.

hab ([HAB](#)) - returns
Anchor block handle.

NULLHANDLE

Invalid *hwnd* parameter

Other

Anchor block handle.

WinQueryAnchorBlock - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinQueryAnchorBlock - Example Code

This function obtains the anchor block handle of the caller.

```

WinQueryAtomLength

WinQueryAtomLength - Syntax

This function queries the length of an atom represented by the specified atom.

```
#define INCL_WINATOM /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HATOMTBL    hatomtblAtomTbl; /* Atom-table handle. */
ATOM        atom;           /* Atom whose associated character-string length is to be returned. */
ULONG       ulretlen;        /* String length. */

ulretlen = WinQueryAtomLength(hatomtblAtomTbl,
                              atom);
```

WinQueryAtomLength Parameter - hatomtblAtomTbl

hatomtblAtomTbl ([HATOMTBL](#)) - input
Atom-table handle.

The handle returned from a previous [WinCreateAtomTable](#) or [WinQuerySystemAtomTable](#) function.

WinQueryAtomLength Parameter - atom

atom ([ATOM](#)) - input
Atom whose associated character-string length is to be returned.

WinQueryAtomLength Return Value - ulretlen

ulretlen ([ULONG](#)) - returns
String length.

0

The specified atom or the atom table is invalid.

Other

The length of the character string associated with the atom **excluding** the null terminating byte. Integer atoms always return a length of six.

WinQueryAtomLength - Parameters

hatomtblAtomTbl ([HATOMTBL](#)) - input
Atom-table handle.

The handle returned from a previous [WinCreateAtomTable](#) or [WinQuerySystemAtomTable](#) function.

atom ([ATOM](#)) - input
Atom whose associated character-string length is to be returned.

ulretlen ([ULONG](#)) - returns
String length.

0

The specified atom or the atom table is invalid.

Other

The length of the character string associated with the atom **excluding** the null terminating byte. Integer atoms always return a length of six.

WinQueryAtomLength - Remarks

The purpose of this function is to allow an application to determine the size of buffer to use in the [WinQueryAtomName](#) call.

WinQueryAtomLength - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HATOMTBL (0x1013)
An invalid atom-table handle was specified.

PMERR_INVALID_ATOM (0x1014)
The specified atom does not exist in the atom table.

WinQueryAtomName

WinQueryAtomName - Syntax

This function returns an atom name associated with an atom.

```

#define INCL_WINATOM /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HATOMTBL    hatomtblAtomTbl; /* Atom-table handle. */
ATOM        atom;           /* Identifies the character string to be retrieved. */
PSZ         pszBuffer;      /* Buffer to receive the character string. */
ULONG       ulBufferMax;     /* Buffer size in bytes. */
ULONG       ulretlen;        /* Length of retrieved character string. */

ulretlen = WinQueryAtomName(hatomtblAtomTbl,
                           atom, pszBuffer, ulBufferMax);

```

WinQueryAtomName Parameter - hatomtblAtomTbl

hatomtblAtomTbl ([HATOMTBL](#)) - input
Atom-table handle.

The handle returned from a previous [WinCreateAtomTable](#) or [WinQuerySystemAtomTable](#) function.

WinQueryAtomName Parameter - atom

atom ([ATOM](#)) - input
Identifies the character string to be retrieved.

WinQueryAtomName Parameter - pszBuffer

pszBuffer ([PSZ](#)) - output
Buffer to receive the character string.

WinQueryAtomName Parameter - ulBufferMax

ulBufferMax ([ULONG](#)) - input
Buffer size in bytes.

WinQueryAtomName Return Value - ulretlen

ulretlen ([ULONG](#)) - returns
Length of retrieved character string.

0
The specified atom or the atom table is invalid.

Other
The number of bytes copied to the buffer **excluding** the terminating zero.

WinQueryAtomName - Parameters

hatomtblAtomTbl ([HATOMTBL](#)) - input
Atom-table handle.

The handle returned from a previous [WinCreateAtomTable](#) or [WinQuerySystemAtomTable](#) function.

atom ([ATOM](#)) - input
Identifies the character string to be retrieved.

pszBuffer ([PSZ](#)) - output
Buffer to receive the character string.

ulBufferMax ([ULONG](#)) - input
Buffer size in bytes.

ulretlen ([ULONG](#)) - returns
Length of retrieved character string.

0
The specified atom or the atom table is invalid.

Other
The number of bytes copied to the buffer **excluding** the terminating zero.

WinQueryAtomName - Remarks

For integer atoms, the format of the string is "#dddd" where "dddd" are decimal digits in the system code page (an ASCII code page). No leading zeros are generated, and the length can be from 3 through 7 characters.

WinQueryAtomName - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HATOMTBL (0x1013)
An invalid atom-table handle was specified.

PMERR_INVALID_ATOM (0x1014)
The specified atom does not exist in the atom table.

PMERR_INVALID_STRING_PARM (0x100B)
The specified string parameter is invalid.

ULONG       ulcount;        /* Use count of the atom. */

ulcount = WinQueryAtomUsage(hatomtblAtomTbl,
                           atom);
```

WinQueryAtomUsage Parameter - hatomtblAtomTbl

hatomtblAtomTbl ([HATOMTBL](#)) - input
Atom-table handle.

The handle returned from a previous [WinCreateAtomTable](#) or [WinQuerySystemAtomTable](#) function.

WinQueryAtomUsage Parameter - atom

atom ([ATOM](#)) - input
Atom whose use count is to be returned.

WinQueryAtomUsage Return Value - ulcount

ulcount ([ULONG](#)) - returns
Use count of the atom.

65535	Integer atom
0	The specified atom or the atom table is invalid
Other	Use count.

WinQueryAtomUsage - Parameters

hatomtblAtomTbl ([HATOMTBL](#)) - input
Atom-table handle.

The handle returned from a previous [WinCreateAtomTable](#) or [WinQuerySystemAtomTable](#) function.

atom ([ATOM](#)) - input
Atom whose use count is to be returned.

ulcount ([ULONG](#)) - returns
Use count of the atom.

65535	Integer atom
0	The specified atom or the atom table is invalid
Other	Use count.

WinQueryAtomUsage - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HATOMTBL (0x1013)
An invalid atom-table handle was specified.

PMERR_INVALID_ATOM (0x1014)
The specified atom does not exist in the atom table.

WinQueryButtonCheckstate

WinQueryButtonCheckstate - Syntax

This macro returns the checked state of the button control specified.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND     hwndDlg;      /* Dialog window handle. */
USHORT    usId;         /* Button control identity. */
USHORT    usRetChkst;   /* Returns the checkstate of the specified button control. */

usRetChkst = WinQueryButtonCheckstate(hwndDlg,
                                       usId);
```

WinQueryButtonCheckstate Parameter - hwndDlg

hwndDlg ([HWND](#)) - input
Dialog window handle.

WinQueryButtonCheckstate Parameter - usId

usId ([USHORT](#)) - input
Button control identity.

WinQueryButtonCheckstate Return Value - usRetChkst

usRetChkst ([USHORT](#)) - returns
Returns the checkstate of the specified button control.

WinQueryButtonCheckstate - Parameters

hwndDlg ([HWND](#)) - input
Dialog window handle.

usId ([USHORT](#)) - input
Button control identity.

usRetChkst ([USHORT](#)) - returns
Returns the checkstate of the specified button control.

WinQueryButtonCheckstate - Remarks

This macro expands to:

```
#define WinQueryButtonCheckstate(hwndDlg, usId)
( (USHORT)WinSendDlgItemMsg(hwndDlg,
                             usId,
                             BM_QUERYCHECK,
                             (MPARAM)NULL,
                             (MPARAM)NULL) )
```

This function requires the existence of a message queue.

WinQueryCapture

WinQueryCapture - Syntax

This function returns the handle of the window that has the pointer captured.

```
#define INCL_WININPUT /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwndDesktop; /* Desktop-window handle. */
HWND    hwnd;         /* Handle of the window with the pointer captured. */

hwnd = WinQueryCapture(hwndDesktop);
```

WinQueryCapture Parameter - hwndDesktop

hwndDesktop ([HWND](#)) - input
Desktop-window handle.

HWND_DESKTOP	The desktop-window handle
Other	Specified desktop-window handle.

WinQueryCapture Return Value - hwnd

hwnd ([HWND](#)) - returns
Handle of the window with the pointer captured.

NULLHANDLE	No window has the pointer captured, or an error occurred
Handle	Handle of the window with the pointer captured.

WinQueryCapture - Parameters

hwndDesktop ([HWND](#)) - input
Desktop-window handle.

HWND_DESKTOP	The desktop-window handle
Other	Specified desktop-window handle.

hwnd ([HWND](#)) - returns
Handle of the window with the pointer captured.

NULLHANDLE	No window has the pointer captured, or an error occurred
Handle	Handle of the window with the pointer captured.

WinQueryCapture - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinQueryClassInfo

WinQueryClassInfo - Syntax

This function returns window class information.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;           /* Anchor-block handle. */
PSZ      PSZClassName;  /* Class name. */
PCLASSINFO PclsClassInfo; /* Class information structure. */
BOOL     rc;           /* Class-exists indicator. */

rc = WinQueryClassInfo(hab, PSZClassName,
                       PclsClassInfo);
```

WinQueryClassInfo Parameter - hab

hab (**HAB**) - input
Anchor-block handle.

WinQueryClassInfo Parameter - PSZClassName

PSZClassName (**PSZ**) - input
Class name.

WinQueryClassInfo Parameter - PclsClassInfo

PclsClassInfo (**PCLASSINFO**) - output
Class information structure.

WinQueryClassInfo Return Value - rc

rc (**BOOL**) - returns
Class-exists indicator.

TRUE
Class does exist

FALSE

Class does not exist.

WinQueryClassInfo - Parameters

hnb ([HAB](#)) - input
Anchor-block handle.

PSZClassName ([PSZ](#)) - input
Class name.

PclsiClassInfo ([PCLASSINFO](#)) - output
Class information structure.

rc ([BOOL](#)) - returns
Class-exists indicator.

TRUE

Class does exist

FALSE

Class does not exist.

WinQueryClassInfo - Remarks

PSZClassName is either an application-specified name (as defined by the [WinRegisterClass](#) call) or the name of a preregistered WC_* class; Preregistered class names are of the form #nnnnn, where nnnnn is up to five digits corresponding to the value of the WC_* class name constant.

This function provides information that is needed to create a subclass of a given class (see [WinSubclassWindow](#)).

WinQueryClassInfo - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_INTEGER_ATOM (0x1016)
The specified atom is not a valid integer atom.

PMERR_INVALID_ATOM_NAME (0x1015)
An invalid atom name string was passed.

PMERR_ATOM_NAME_NOT_FOUND (0x1017)
The specified atom name is not in the atom table.

WinQueryClassName

WinQueryClassName - Syntax

This function copies the window class name, as a null-terminated string, into a buffer.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwnd;        /* Window handle. */
LONG    lLength;      /* Length of PCHBuffer. */
PCH      PCHBuffer;    /* Class name. */
LONG     lRetLen;      /* Returned class name length. */

lRetLen = WinQueryClassName(hwnd, lLength,
                             PCHBuffer);
```

WinQueryClassName Parameter - hwnd

hwnd (**HWND**) - input
Window handle.

If this window is of any of the preregistered WC_* classes the class name returned in the *PCHBuffer* parameter is in the form "#nnnnn", where "nnnnn" is a group of up to five digits that corresponds to the value of the WC_* class name constant.

WinQueryClassName Parameter - lLength

lLength (**LONG**) - input
Length of *PCHBuffer*.

It must be greater than 0.

WinQueryClassName Parameter - PCHBuffer

PCHBuffer (**PCH**) - output
Class name.

If the class name is longer than (*lLength*-1) only the first (*lLength*-1) characters of class name are copied.

WinQueryClassName Return Value - lRetLen

lRetLen (**LONG**) - returns
Returned class name length.

This is the length, *excluding* the null-termination character.

WinQueryClassName - Parameters

hwnd ([HWND](#)) - input
Window handle.

If this window is of any of the preregistered `WC_*` classes the class name returned in the *PCHBuffer* parameter is in the form `"#nnnnn"`, where `"nnnnn"` is a group of up to five digits that corresponds to the value of the `WC_*` class name constant.

Length ([LONG](#)) - input
Length of *PCHBuffer*.

It must be greater than 0.

PCHBuffer ([PCH](#)) - output
Class name.

If the class name is longer than $(Length-1)$ only the first $(Length-1)$ characters of class name are copied.

IRetLen ([LONG](#)) - returns
Returned class name length.

This is the length, *excluding* the null-termination character.

WinQueryClassName - Errors

Possible returns from [WinGetLastError](#)

`PMERR_INVALID_HWND (0x1001)`
An invalid window handle was specified.

`PMERR_INVALID_STRING_PARM (0x100B)`
The specified string parameter is invalid.

WinQueryClassThunkProc

WinQueryClassThunkProc - Syntax

This call queries the pointer-conversion procedure associated with a class.

```
#define INCL_WINTHUNKAPI /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

PSZ      pszClassName; /* Window-class name. */
PFN      thunkpr;      /* Pointer-conversion procedure identifier. */

thunkpr = WinQueryClassThunkProc(pszClassName);
```

WinQueryClassThunkProc Parameter - pszClassName

pszClassName ([PSZ](#)) - input
Window-class name.

WinQueryClassThunkProc Return Value - thunkpr

thunkpr ([PFN](#)) - returns
Pointer-conversion procedure identifier.

NULL	No pointer-conversion procedure is associated with this class.
Other	Identifier of the pointer-conversion procedure associated with this class.

WinQueryClassThunkProc - Parameters

pszClassName ([PSZ](#)) - input
Window-class name.

thunkpr ([PFN](#)) - returns
Pointer-conversion procedure identifier.

NULL	No pointer-conversion procedure is associated with this class.
Other	Identifier of the pointer-conversion procedure associated with this class.

WinQueryClipbrdData

WinQueryClipbrdData - Syntax

This function obtains a handle to the current clipboard data with a specified format.

```

#define INCL_WINCLIPBOARD /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;      /* Anchor-block handle. */
ULONG    fmt;      /* Format of the data to be accessed. */
ULONG    ulRet;    /* Handle to the clipboard data. */

ulRet = WinQueryClipbrdData(hab, fmt);

```

WinQueryClipbrdData Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinQueryClipbrdData Parameter - fmt

fmt ([ULONG](#)) - input
Format of the data to be accessed.

In addition to the predefined formats, private formats can be created using the standard system atom manager. The following is the list of standard clipboard formats:

CF_TEXT	Text format. Each line ends with a carriage-return/line-feed combination. Tab characters separate fields within a line. A NULL character signals the end of the data.
CF_DSPTEXT	Text display format associated with private format.
CF_BITMAP	Bit map.
CF_DSPBITMAP	Bit-map display format associated with private format.
CF_METAFILE	Metafile.
CF_DSPMETAFILE	Metafile display format associated with private format.
CF_PALETTE	Palette.

WinQueryClipbrdData Return Value - ulRet

ulRet ([ULONG](#)) - returns
Handle to the clipboard data.

0	Format does not exist, or an error occurred
Other	Handle to the clipboard data.

WinQueryClipbrdData - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

fmt ([ULONG](#)) - input
Format of the data to be accessed.

In addition to the predefined formats, private formats can be created using the standard system atom manager. The following is the list of standard clipboard formats:

CF_TEXT	Text format. Each line ends with a carriage-return/line-feed combination. Tab characters separate fields within a line. A NULL character signals the end of the data.
CF_DSPTEXT	Text display format associated with private format.
CF_BITMAP	Bit map.
CF_DSPBITMAP	Bit-map display format associated with private format.
CF_METAFILE	Metafile.
CF_DSPMETAFILE	Metafile display format associated with private format.
CF_PALETTE	Palette.

ulRet ([ULONG](#)) - returns
Handle to the clipboard data.

0	Format does not exist, or an error occurred
Other	Handle to the clipboard data.

WinQueryClipbrdData - Remarks

The returned data handle must not be used after the [WinCloseClipbrd](#) function is called. For this reason, the application must either copy the data (if required for long-term use) or process the data before the [WinCloseClipbrd](#) function is called. The application must neither free the data handle itself, nor leave it locked in any way.

Information about the format of the data in the clipboard can be obtained from [WinQueryClipbrdFmtInfo](#).

WinQueryClipbrdFmtInfo

WinQueryClipbrdFmtInfo - Syntax

This function determines whether a particular format of data is present in the clipboard, and if so, provides information about that format.

```
#define INCL_WINCLIPBOARD /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
ULONG    fmt;          /* Format of the data to be queried. */
PULONG   prgfFmtInfo;  /* Memory model and usage flags. */
BOOL     rc;           /* Format-exists indicator. */

rc = WinQueryClipbrdFmtInfo(hab, fmt, prgfFmtInfo);
```

WinQueryClipbrdFmtInfo Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinQueryClipbrdFmtInfo Parameter - fmt

fmt ([ULONG](#)) - input

Format of the data to be queried.

In addition to the predefined formats, private formats can be created using the standard system atom manager. The following is the list of standard clipboard formats:

CF_BITMAP

Bit map.

CF_DSPBITMAP

Bit-map display format associated with private format.

CF_DSPMETAFILE

Metafile display format associated with private format.

CF_DSPTTEXT

Text display format associated with private format.

CF_METAFILE

Metafile.

CF_PALETTE

Palette.

CF_TEXT

Text format. Each line ends with a carriage-return/line-feed combination. Tab characters separate fields within a line. A NULL character signals the end of the data.

WinQueryClipbrdFmtInfo Parameter - prgfFmtInfo

prgfFmtInfo ([PULONG](#)) - output

Memory model and usage flags.

These are the usage flags set by the setting application; that is, the CFI_* flags of the *flFmtInfo* parameter of the [WinSetClipbrdData](#) function.

If the format is CF_BITMAP, CF_DSPBITMAP, CF_METAFILE or CF_DSPMETAFILE, *prgfFmtInfo* is set to CFI_HANDLE. If the format is CF_TEXT or CF_DSPTTEXT, *prgfFmtInfo* is set to CFI_POINTER. If the format is user-defined, *prgfFmtInfo* is set to the value used in the [WinSetClipbrdData](#) function.

WinQueryClipbrdFmtInfo Return Value - rc

rc ([BOOL](#)) - returns

Format-exists indicator.

TRUE

fmt exists in the clipboard and *prgfFmtInfo* is set

FALSE

fmt does not exist in the clipboard and *prgfFmtInfo* is not set.

hab (**HAB**) - input

Anchor-block handle.

fmt (ULONG) - input

Format of the data to be queried.

In addition to the predefined formats, private formats can be created using the standard system atom manager. The following is the list of standard clipboard formats:

CF BITMAP

Bit map.

CF DSPBITMAP

Bit-map display format associated with private format.

CF DSPMETAFILE

Metafile display format associated with private format.

CF_DSPTTEXT

Text display format associated with private format.

CF METAFILE

Metafile.

CF PALETTE

Palette.

CF TEXT

Text format. Each line ends with a carriage-return/line-feed combination. Tab characters separate fields within a line. A NULL character signals the end of the data.

prgfFmtInfo (**PULONG**) - output

Memory model and usage flags.

These are the usage flags set by the setting application; that is, the `CFL_*` flags of the `//FmtInfo` parameter of the `WinSetClipbrdData` function.

If the format is CF_BITMAP, CF_DSPBITMAP, CF_METAFILE or CF_DSPMETAFILE, *prgFmtInfo* is set to CFI_HANDLE. If the format is CF_TEXT or CF_DSPTXT, *prgFmtInfo* is set to CFI_POINTER. If the format is user-defined, *prgFmtInfo* is set to the value used in the [WinSetClipbrdData](#) function.

rc (BOOL) - returns

Format-exists indicator.

TRUE

fmt exists in the clipboard and *prgfFmtInfo* is set

FALSE

fmt does not exist in the clipboard and *prgfFmtInfo* is not set.

This function does not cause the data to be rendered.

Applications can put information in the clipboard in their own private format. Use the following function calls to create and query a private format:

[illegible]

```
        "Private Data Type"),
    flFmtInfo);
```

```
ulData = WinQueryClipbrdData(hab,
                             WinFindAtom(WinQuerySystemAtomTable(),
                                           "Private Data Type"));
```

WinQueryClipbrdOwner

WinQueryClipbrdOwner - Syntax

This function obtains any current clipboard owner window.

```
#define INCL_WINCLIPBOARD /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;                /* Anchor-block handle. */
HWND     hwndClipbrdOwner;   /* Window handle of the current clipboard owner. */

hwndClipbrdOwner = WinQueryClipbrdOwner(hab);
```

WinQueryClipbrdOwner Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinQueryClipbrdOwner Return Value - hwndClipbrdOwner

hwndClipbrdOwner ([HWND](#)) - returns
Window handle of the current clipboard owner.

NULLHANDLE	If the clipboard is not owned by any window, or if an error occurred.
Other	Window handle of the current clipboard owner.

WinQueryClipbrdOwner - Parameters

hab ([HAB](#)) - input

Anchor-block handle.

hwndClipbrdOwner ([HWND](#)) - returns
Window handle of the current clipboard owner.

NULLHANDLE

If the clipboard is not owned by any window, or if an error occurred.

Other

Window handle of the current clipboard owner.

WinQueryClipbrdViewer Return Value - hwndClipbrdViewer

hwndClipbrdViewer ([HWND](#)) - returns
Current clipboard viewer window handle.

NULLHANDLE	Clipboard does not have a current viewer window, or an error occurred
Other	Current clipboard viewer window handle.

WinQueryClipbrdViewer - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

hwndClipbrdViewer ([HWND](#)) - returns
Current clipboard viewer window handle.

NULLHANDLE	Clipboard does not have a current viewer window, or an error occurred
Other	Current clipboard viewer window handle.

WinQueryControlColors

WinQueryControlColors - Syntax

This function queries the colors currently being used by a control window.

Note: If you are interested in the default colors used by PM controls, see [Colors Used by PM Controls](#).

```
#define INCL_WINSYS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwnd;      /* Window handle. */
LONG      clrType;    /* Control color index. */
ULONG     fCtlColor;  /* Control Color Flags. */
ULONG     cCtlColor;  /* Number of items available in pCtlColor. */
PCTL_COLOR pCtlColor; /* Array of control colors, each comprising an index and value pair. */
LONG      rc;         /* Number of control colors returned in pCtlColor. */

rc = WinQueryControlColors(hwnd, clrType,
                           fCtlColor, cCtlColor, pCtlColor);
```

WinQueryControlColors Parameter - hwnd

hwnd (**HWND**) - input
Window handle.

WinQueryControlColors Parameter - clrType

clrType (**LONG**) - input
Control color index.

Must be one of the following control color indexes:.

CCT_STATIC	Static bitmap.
CCT_STATICTEXT	Static text.
CCT_GROUPBOX	Group Box.
CCT_PUSHBUTTON	Push button.
CCT_CHECKBOX	Check box.
CCT_RADIOBUTTON	Radio button.
CCT_ENTRYFIELD	Entry field.
CCT_LISTBOX	List box.
CCT_COMBOBOX	Combo box.
CCT_SCROLLBAR	Scroll bar.
CCT_FRAME	Window frame.
CCT_MENU	Menu.

CCT_TITLEBAR	Title bar.
CCT_SPINBUTTON	Spin button.
CCT_SLIDER	Slider.
CCT_CIRCULARSLIDER	Circular slider.
CCT_VALUESET	Value set.
CCT_MLE	Multiple line entry field.
CCT_CONTAINER	Container.
CCT_NOTEBOOK	Notebook.

WinQueryControlColors Parameter - fCtlColor

fCtlColor ([ULONG](#)) - input
Control Color Flags.

CCF_GLOBAL	Query global default colors (default)
CCF_APPLICATION	Query application default colors (used on current thread)
CCF_COUNTCOLORS	Return the number of color indexes used by a control window
CCF_ALLCOLORS	Return information on all colors used by a control window

WinQueryControlColors Parameter - cCtlColor

cCtlColor ([ULONG](#)) - input
Number of items available in *pCtlColor*.

If CCF_ALLCOLORS is specified, this value is the maximum number of items that can be returned in *pCtlColor*. Otherwise, this value is the number of color indexes being queried in *pCtlColor*.

If CCF_COUNTCOLORS is specified, this value is 0.

WinQueryControlColors Parameter - pCtlColor

pCtlColor ([PCTLCOLOR](#)) - in/out
Array of control colors, each comprising an index and value pair.

WinQueryControlColors Return Value - rc

rc (**LONG**) - returns
Number of control colors returned in *pCtlColor*.

TRUE
FALSE

Number of control colors returned.
Error, invalid parameters.

WinQueryControlColors - Parameters

hwnd (**HWND**) - input
Window handle.

clrType (**LONG**) - input
Control color index.

Must be one of the following control color indexes:.

CCT_STATIC
Static bitmap.

CCT_STATICTEXT
Static text.

CCT_GROUPBOX
Group Box.

CCT_PUSHBUTTON
Push button.

CCT_CHECKBOX
Check box.

CCT_RADIOBUTTON
Radio button.

CCT_ENTRYFIELD
Entry field.

CCT_LISTBOX
List box.

CCT_COMBOBOX
Combo box.

CCT_SCROLLBAR
Scroll bar.

CCT_FRAME
Window frame.

CCT_MENU
Menu.

CCT_TITLEBAR
Title bar.

CCT_SPINBUTTON
Spin button.

CCT_SLIDER
Slider.

CCT_CIRCULARSLIDER
Circular slider.

CCT_VALUESET
Value set.

CCT_MLE
Multiple line entry field.

CCT_CONTAINER
Container.

CCT_NOTEBOOK
Notebook.

fCtlColor (**ULONG**) - input
Control Color Flags.

CCF_GLOBAL
Query global default colors (default)

CCF_APPLICATION
Query application default colors (used on current thread)

CCF_COUNTCOLORS
Return the number of color indexes used by a control window

CCF_ALLCOLORS
Return information on all colors used by a control window

cCtlColor ([ULONG](#)) - input

Number of items available in *pCtlColor*.

If CCF_ALLCOLORS is specified, this value is the maximum number of items that can be returned in *pCtlColor*. Otherwise, this value is the number of color indexes being queried in *pCtlColor*.

If CCF_COUNTCOLORS is specified, this value is 0.

pCtlColor ([PCTLCOLOR](#)) - in/out

Array of control colors, each comprising an index and value pair.

rc ([LONG](#)) - returns

Number of control colors returned in *pCtlColor*.

TRUE

Number of control colors returned.

FALSE

Error, invalid parameters.

WinQueryControlColors - Remarks

This function returns the colors (one or more) that are currently being used by a control window of the type specified by *clrType*. If *hwnd* is a valid control window handle, the colors being used by that window are returned, including any presentation parameters it might be using. If *hwnd* is set to HWND_DESKTOP, the default colors being used by that window are returned.

To find out the default control colors for the current thread, specify CCF_APPLICATION. Be sure to issue the call to WinQueryColors from the same thread that created the control windows, otherwise the information returned will be incorrect.

To get all the colors used by a control window returned at once, specify CCF_ALLCOLORS. You can call WinQueryColors with CCF_COUNTCOLORS first to determine the buffer size you will need for the color information.

Each item in the returned array contains an index and value pair (CTL_COLOR). If CCF_ALLCOLORS and CCF_COUNTCOLORS are not set, each item's index should be set to a valid CCI_* constant for which a value is to be returned. The values returned in the array are always valid RGB colors (including SYSCLR_* values, which are actually indexes but can be used by graphics functions in RGB mode).

If an invalid CCI_* index is specified, CCF_NOTFOUND is returned.

Note: This function can only be used for querying the colors of standard PM controls.

WinQueryControlColors - Example Code

This example first queries the count of colors used by a push button. Then it queries all the colors used by push buttons in the application.

```
/* ***** */
/* Query the number of colors used by a push button. */
/* ***** */

cCount = WinQueryControlColors(
    HWND_DESKTOP,          /* Desktop window handle */
    CCT_PUSHBUTTON,        /* Select push button */
    CCF_COUNTCOLORS,       /* Count number of colors */
    0, 0);

pactlColor = (PCTLCOLOR)malloc(sizeof(CTLCOLOR) * cCount);

/* ***** */
/* Query all the colors used by push buttons in application. */
/* ***** */

WinQueryControlColors(HWND_DESKTOP,          /* Desktop window handle */
    CCT_PUSHBUTTON,        /* Select push button */
    CCF_ALLCOLORS |        /* Return all colors ... */
    CCF_APPLICATION,       /* ... for application */
    cCount,                /* Size of array */
    pactlColor);           /* Buffer for color data */
```

WinQueryCp

WinQueryCp - Syntax

This function returns the queue code page for the specified message queue.

```
#define INCL_WINCOUNTRY /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HMQ      hmq;          /* Message queue. */
ULONG    ulCodePage;    /* Code page. */

ulCodePage = WinQueryCp(hmq);
```

WinQueryCp Parameter - hmq

hmq ([HMQ](#)) - input
Message queue.

WinQueryCp Return Value - ulCodePage

ulCodePage ([ULONG](#)) - returns
Code page.

0	Error occurred
Other	Queue code page for the specified message queue.

WinQueryCp - Parameters

hmq ([HMQ](#)) - input
Message queue.

ulCodePage ([ULONG](#)) - returns
Code page.

0	Error occurred
Other	Queue code page for the specified message queue.

WinQueryCp - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HMQ (0x1002)
An invalid message-queue handle was specified.

WinQueryCpList

WinQueryCpList - Syntax

This function queries available code pages.

```
#define INCL_WINCOUNTRY /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
ULONG    ulcount;      /* Maximum number of code pages returned. */
PULONG   aulCodepage;  /* Code page list. */
ULONG    ulTotCount;   /* Total number of code pages available. */

ulTotCount = WinQueryCpList(hab, ulcount,
                           aulCodepage);
```

WinQueryCpList Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinQueryCpList Parameter - ulcount

ulcount ([ULONG](#)) - input
Maximum number of code pages returned.

WinQueryCpList Parameter - aulCodepage

aulCodepage ([PULONG](#)) - output
Code page list.

An array of *ulcount* elements, that contains a list of code pages available to the program.

For more information about code pages, see

WinQueryCpList Return Value - ulTotCount

ulTotCount ([ULONG](#)) - returns
Total number of code pages available.

0	An error occurred
Other	Total number of code pages available.

WinQueryCpList - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

ulcount ([ULONG](#)) - input
Maximum number of code pages returned.

aulCodepage ([PULONG](#)) - output
Code page list.

An array of *ulcount* elements, that contains a list of code pages available to the program.

For more information about code pages, see

ulTotCount ([ULONG](#)) - returns
Total number of code pages available.

0	An error occurred
Other	Total number of code pages available.

WinQueryCpList - Errors

Possible returns from [WinGetLastError](#)

PMERR_PARAMETER_OUT_OF_RANGE (0x1003)
The value of a parameter was not within the defined valid range for that parameter.

WinQueryCursorInfo

WinQueryCursorInfo - Syntax

This function obtains information about any current cursor.

```
#define INCL_WINCursors /* Or use INCL_WIN, INCL_PM, */  
#include <os2.h>  
  
HWND      hwndDesktop; /* Desktop-window handle. */  
PCURSORINFO pcsriCursorInfo; /* Cursor information. */  
BOOL      rc; /* Current-cursor indicator. */  
  
rc = WinQueryCursorInfo(hwndDesktop, pcsriCursorInfo);
```

WinQueryCursorInfo Parameter - hwndDesktop

hwndDesktop ([HWND](#)) - input
Desktop-window handle.

HWND_DESKTOP	The desktop-window handle
Other	Specified desktop-window handle.

WinQueryCursorInfo Parameter - pcsriCursorInfo

pcsriCursorInfo ([PCURSORINFO](#)) - output
Cursor information.

The values are equivalent to the parameters of the [WinCreateCursor](#) function except that *ulrgf* never includes the CURSOR_SETPOS option.

The size and position of the cursor are returned in window coordinates relative to the window identified by the parameter of the structure.

WinQueryCursorInfo Return Value - rc

rc ([BOOL](#)) - returns
Current-cursor indicator.

TRUE

Cursor exists

FALSE

Cursor does not exist, *pcsriCursorInfo* is not updated by this call.

WinQueryCursorInfo - Parameters

hwndDeskTop ([HWND](#)) - input
Desktop-window handle.

HWND_DESKTOP

The desktop-window handle

Other

Specified desktop-window handle.

pcsriCursorInfo ([PCCURSORINFO](#)) - output
Cursor information.

The values are equivalent to the parameters of the [WinCreateCursor](#) function except that *ulrgf* never includes the CURSOR_SETPOS option.

The size and position of the cursor are returned in window coordinates relative to the window identified by the parameter of the structure.

rc ([BOOL](#)) - returns
Current-cursor indicator.

TRUE

Cursor exists

FALSE

Cursor does not exist, *pcsriCursorInfo* is not updated by this call.

WinQueryCursorInfo - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinQueryDesktopBkgnd

WinQueryDesktopBkgnd - Syntax

This function returns the desktop structure, which contains the information about the current state of the desktop background.

```

#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwndDesktop; /* Desktop-window handle. */
PDESKTOP  pdsk;        /* Desktop-state structure. */
BOOL      rc;          /* Success indicator. */

rc = WinQueryDesktopBkgnd(hwndDesktop, pdsk);

```

WinQueryDesktopBkgnd Parameter - hwndDesktop

hwndDesktop (**HWND**) - input
Desktop-window handle.

HWND_DESKTOP	The desktop window
Other	Specified desktop window.

WinQueryDesktopBkgnd Parameter - pdsk

pdsk (**PDESKTOP**) - output
Desktop-state structure.

WinQueryDesktopBkgnd Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Desktop-window status provided
FALSE	Desktop-window status not provided.

WinQueryDesktopBkgnd - Parameters

hwndDesktop (**HWND**) - input
Desktop-window handle.

HWND_DESKTOP	The desktop window
Other	Specified desktop window.

pdesk ([PDESKTOP](#)) - output
Desktop-state structure.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Desktop-window status provided
FALSE	Desktop-window status not provided.

WinQueryDesktopBkgnd - Remarks

This function allows an application to query the background information of the desktop window. This application must be acting as the OS/2 PM shell in place of the IBM supplied shell. If the IBM supplied shell is executing it maintains control of the background of the desktop window, and WinQueryDesktopBkgnd will have no effect on the desktop window background, but will indicate a successful return code.

WinQueryDesktopBkgnd - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinQueryDesktopBkgnd - Related Functions

Related Functions

WinQueryDesktopBkgnd - Example Code

This example uses WinQueryDesktopBkgnd to query the current desktop background bit map before setting it to a new bit map with WinSetDesktopBkgnd.

```
#define INCL_WINDESKTOP
#define INCL_WINWINDOWMGR
#include <OS2.H>
HAB hab;
HWND hwndDeskTop;
DESKTOP DeskTopState;
HBITMAP hbm;
HBITMAP hbm_user;

WinQueryDesktopBkgnd(HWND_DESKTOP,
                    &DeskTopState);

if (hbm_user != DeskTopState.hbm)
```

```

{
    DeskTopState.fl = SDT_LOADFILE;
    /* the szFile is used to load the bit map because */
    /* the fl parameter is set to SDT_LOADFILE.      */
    strcpy(DeskTopState.szFile, "fruit.bmp");
    DeskTopState.hbm = hbm_user;
    WinSetDesktopBkgnd(hwndDeskTop,
                      &DeskTopState);
}

```

WinQueryDesktopWindow

WinQueryDesktopWindow - Syntax

This function returns the desktop-window handle.

```

#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;           /* Anchor-block handle. */
HDC      hdc;           /* Device-context handle. */
HWND     hwndDeskTop;   /* Desktop-window handle. */

hwndDeskTop = WinQueryDesktopWindow(hab, hdc);

```

WinQueryDesktopWindow Parameter - hab

hab (**HAB**) - input
Anchor-block handle.

WinQueryDesktopWindow Parameter - hdc

hdc ([HDC](#)) - input
Device-context handle.

NULLHANDLE
Default device (the screen).

WinQueryDesktopWindow Return Value - hwndDeskTop

hwndDeskTop ([HWND](#)) - returns
Desktop-window handle.

NULLHANDLE
Error occurred

Other
Desktop-window handle.

WinQueryDesktopWindow - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

hdc ([HDC](#)) - input
Device-context handle.

NULLHANDLE
Default device (the screen).

hwndDeskTop ([HWND](#)) - returns
Desktop-window handle.

NULLHANDLE
Error occurred

Other
Desktop-window handle.

WinQueryDesktopWindow - Remarks

Only the screen device supports windowing.

Many of the calls that require a desktop-window handle accept HWND_DESKTOP instead. For example, [WinCreateWindow](#) accepts HWND_DESKTOP for the parent-window handle to create a main window that is a child of the desktop window.

WinQueryDesktopWindow - Errors

Possible returns from [WinGetLastError](#)

PMERR_INV_HDC (0x207C)

An invalid device-context handle or (micro presentation space) presentation-space handle was specified.

WinQueryDlgItemShort

WinQueryDlgItemShort - Syntax

This function converts the text of a dialog item into an integer value.

```
#define INCL_WINDIALOGS /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HWND     hwndDlg; /* Parent-window handle. */
ULONG     idItem; /* Identity of the child window whose text is to be converted. */
PSHORT    psResult; /* Integer value resulting from the conversion. */
BOOL      fSigned; /* Sign indicator. */
BOOL      rc; /* Success indicator. */

rc = WinQueryDlgItemShort(hwndDlg, idItem,
    psResult, fSigned);
```

WinQueryDlgItemShort Parameter - hwndDlg

hwndDlg (**HWND**) - input
Parent-window handle.

WinQueryDlgItemShort Parameter - idItem

idItem (**ULONG**) - input
Identity of the child window whose text is to be converted.

It must be greater or equal to 0 and less or equal to 0xFFFF.

WinQueryDlgItemShort Parameter - psResult

psResult (**PSHORT**) - output
Integer value resulting from the conversion.

WinQueryDlgItemShort Parameter - fSigned

fSigned (BOOL) - input
Sign indicator.

TRUE	Signed text. It is inspected for a minus sign (-).
FALSE	Unsigned text.

WinQueryDlgItemShort Return Value - rc

rc (BOOL) - returns
Success indicator.

TRUE	Successful conversion
FALSE	Error occurred.

WinQueryDlgItemShort - Parameters

hwndDlg (HWND) - input
Parent-window handle.

idItem (ULONG) - input
Identity of the child window whose text is to be converted.

It must be greater or equal to 0 and less or equal to 0xFFFF.

psResult (PSHORT) - output
Integer value resulting from the conversion.

fSigned (BOOL) - input
Sign indicator.

TRUE	Signed text. It is inspected for a minus sign (-).
FALSE	Unsigned text.

rc (BOOL) - returns
Success indicator.

TRUE	Successful conversion
FALSE	Error occurred.

WinQueryDlgItemShort - Remarks

This function is useful for converting a numerical input field into a binary number for further processing. The text of a dialog item is assumed to be an ASCII string.

This function is valid for any window with children. However, it is typically used for dialog items in a dialog window.

WinQueryDlgItemShort - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinQueryDlgItemText

WinQueryDlgItemText - Syntax

This function queries a text string in a dialog item.

```
#define INCL_WINDIALOGS /* Or use INCL_WIN, INCL_PM, Also in COMMON section */  
#include <os2.h>  
  
HWND    hwndDlg; /* Parent-window handle. */  
ULONG    idItem; /* Identity of the child window whose text is to be queried. */  
LONG     lMaxText; /* Length of pszText. */  
PSZ      pszText; /* Output string. */  
ULONG    ulRetLen; /* Actual number of characters returned. */  
  
ulRetLen = WinQueryDlgItemText(hwndDlg, idItem,  
                                lMaxText, pszText);
```

WinQueryDlgItemText Parameter - hwndDlg

hwndDlg ([HWND](#)) - input
Parent-window handle.

WinQueryDlgItemText Parameter - idItem

idItem ([ULONG](#)) - input
Identity of the child window whose text is to be queried.

It must be greater or equal to 0 and less or equal to 0xFFFF.

WinQueryDlgItemText Parameter - IMaxText

IMaxText ([LONG](#)) - input
Length of *pszText*.

It must be greater or equal to 0.

WinQueryDlgItemText Parameter - pszText

pszText ([PSZ](#)) - output
Output string.

This is the text string that is obtained from the dialog item.

WinQueryDlgItemText Return Value - ulRetLen

ulRetLen ([ULONG](#)) - returns
Actual number of characters returned.

0	Error occurred
Other	Actual number of characters returned, not including the null-terminating character. The maximum value is (<i>IMaxText</i> -1).

WinQueryDlgItemText - Parameters

hwndDlg ([HWND](#)) - input
Parent-window handle.

idItem ([ULONG](#)) - input
Identity of the child window whose text is to be queried.

It must be greater or equal to 0 and less or equal to 0xFFFF.

IMaxText ([LONG](#)) - input

Length of *pszText*.

It must be greater or equal to 0.

pszText ([PSZ](#)) - output
Output string.

This is the text string that is obtained from the dialog item.

ulRetLen ([ULONG](#)) - returns
Actual number of characters returned.

0

Error occurred

Other

Actual number of characters returned, not including the null-terminating character. The maximum value is (*lMaxText*-1).

WinQueryDlgItemText - Remarks

This function is valid for any window with children. However, it is typically used for dialog items in a dialog window.

WinQueryDlgItemText - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinQueryDlgItemTextLength

WinQueryDlgItemTextLength - Syntax

This function queries the length of the text string in a dialog item, not including any null termination character.

```

#define INCL_WINDIALOGS /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HWND    hwndDlg; /* Parent-window handle. */
ULONG   idItem; /* Identity of the child window whose text is to be queried. */
LONG     lRetLen; /* Length of text. */

lRetLen = WinQueryDlgItemTextLength(hwndDlg,
    idItem);

```

WinQueryDlgItemTextLength Parameter - hwndDlg

hwndDlg ([HWND](#)) - input
Parent-window handle.

WinQueryDlgItemTextLength Parameter - idItem

idItem ([ULONG](#)) - input
Identity of the child window whose text is to be queried.

It must be greater or equal to 0 and less or equal to 0xFFFF.

WinQueryDlgItemTextLength Return Value - IRetLen

IRetLen ([LONG](#)) - returns
Length of text.

0
Error occurred

Other
Length of text.

WinQueryDlgItemTextLength - Parameters

hwndDlg ([HWND](#)) - input
Parent-window handle.

idItem ([ULONG](#)) - input
Identity of the child window whose text is to be queried.

It must be greater or equal to 0 and less or equal to 0xFFFF.

IRetLen ([LONG](#)) - returns
Length of text.

0
Error occurred

Other
Length of text.

WinQueryDlgItemTextLength - Remarks

This function is valid for any window with children. However, it is typically used for dialog items in a dialog window.

WinQueryFocus

WinQueryFocus - Syntax

This function returns the focus window. It is NULLHANDLE if there is no focus window.

```
#define INCL_WININPUT /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND     hwndDesktop; /* Desktop-window handle. */
HWND     hwndFocus;   /* Focus-handle. */

hwndFocus = WinQueryFocus(hwndDesktop);
```

WinQueryFocus Parameter - hwndDesktop

- hwndDesktop (HWND)** - input
Desktop-window handle.
 - HWND_DESKTOP
The desktop-window handle
 - Other
Specified desktop-window handle.

WinQueryFocus Return Value - hwndFocus

- hwndFocus (HWND)** - returns
Focus-handle.
 - NULL
Error occurred or no focus window.

WinQueryFocus - Parameters

- hwndDesktop (HWND)** - input
Desktop-window handle.
 - HWND_DESKTOP

	The desktop-window handle
Other	Specified desktop-window handle.
hwndFocus (HWND) - returns Focus-handle.	
NULL	Error occurred or no focus window.

WinQueryFocus - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinQueryHelpInstance

WinQueryHelpInstance - Syntax

This function enables the application to query the instance of the Help Manager associated with the application-supplied window handle.

```
#define INCL_WINHELP /* Or use INCL_WIN, INCL_PM, */  
#include <os2.h>  
  
HWND    hwndApp;    /* Handle of the application window. */  
HWND    hwndHelp;    /* Help Manager window handle. */  
  
hwndHelp = WinQueryHelpInstance(hwndApp);
```

WinQueryHelpInstance Parameter - hwndApp

hwndApp ([HWND](#)) - input
Handle of the application window.

WinQueryHelpInstance Return Value - hwndHelp

hwndHelp ([HWND](#)) - returns
Help Manager window handle.

NULLHANDLE	No Help Manager instance is associated with the application window.
Other	Help Manager window handle.

WinQueryHelpInstance - Parameters

hwndApp ([HWND](#)) - input
Handle of the application window.

hwndHelp ([HWND](#)) - returns
Help Manager window handle.

NULLHANDLE
No Help Manager instance is associated with the application window.

Other
Help Manager window handle.

WinQueryHelpInstance - Remarks

The Help Manager first traces the parent window chain until it is NULLHANDLE or HWND_DESKTOP. Then Help Manager traces the owner chain. If a parent of the owner window exists, the trace begins again with the parent chain.

The window chain will be traced until the Help Manager finds an instance of the Help Manager or until both the parent and owner windows are NULLHANDLE or HWND_DESKTOP.

WinQueryLboxCount

WinQueryLboxCount - Syntax

This macro returns the number of items in the List Box.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND     hwndLbox; /* Listbox handle. */
LONG     lRetNumIt; /* Number of items in the list box. */

lRetNumIt = WinQueryLboxCount(hwndLbox);
```

WinQueryLboxCount Parameter - hwndLbox

hwndLbox ([HWND](#)) - input
Listbox handle.

WinQueryLboxCount Return Value - lRetNumIt

lRetNumIt ([LONG](#)) - returns
Number of items in the list box.

WinQueryLboxCount - Parameters

hwndLbox ([HWND](#)) - input
Listbox handle.

lRetNumIt ([LONG](#)) - returns
Number of items in the list box.

WinQueryLboxCount - Remarks

This macro is defined as:

```
#define WinQueryLboxCount(hwndLbox) \
    ((LONG)WinSendMsg(hwndLbox, \
        LM_QUERYITEMCOUNT, \
        (MPARAM)NULL, \

WinQueryLboxItemText

WinQueryLboxItemText - Syntax

This macro fills the buffer with the text of the indexed item. It returns the length of the text.

```

#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwndLbox; /* List box handle. */
SHORT   index;    /* Index of the listbox item. */
PSZ     psz;      /* Pointer to a null terminated string. */
SHORT   cchMax;   /* Maximum number of characters allocated to the string. */
LONG    lRetTxtL; /* Actual text length copied. */

lRetTxtL = WinQueryLboxItemText(hwndLbox,
                                index, psz, cchMax);

```

WinQueryLboxItemText Parameter - hwndLbox

hwndLbox ([HWND](#)) - input
List box handle.

WinQueryLboxItemText Parameter - index

index ([SHORT](#)) - input
Index of the listbox item.

WinQueryLboxItemText Parameter - psz

psz ([PSZ](#)) - input
Pointer to a null terminated string.

WinQueryLboxItemText Parameter - cchMax

cchMax ([SHORT](#)) - input
Maximum number of characters allocated to the string.

WinQueryLboxItemText Return Value - IRetTxtL

IRetTxtL ([LONG](#)) - returns
Actual text length copied.

WinQueryLboxItemText - Parameters

hwndLbox ([HWND](#)) - input
List box handle.

index ([SHORT](#)) - input
Index of the listbox item.

psz ([PSZ](#)) - input
Pointer to a null terminated string.

cchMax ([SHORT](#)) - input
Maximum number of characters allocated to the string.

IRetTxtL ([LONG](#)) - returns
Actual text length copied.

WinQueryLboxItemText - Remarks

This macro is defined as:

```
#define WinQueryLboxItemText(hwndLbox, index, psz, cchMax) \
    ((LONG)WinSendMessage(hwndLbox, \
        LM_QUERYITEMTEXT, \
        MPFROM2SHORT((index), (cchMax)), \

                                     index);

```

WinQueryLboxItemTextLength Parameter - hwndLbox

hwndLbox ([HWND](#)) - input
Listbox handle.

WinQueryLboxItemTextLength Parameter - index

index ([SHORT](#)) - input
Index of the item in the List Box.

WinQueryLboxItemTextLength Return Value - sRetLen

sRetLen ([SHORT](#)) - returns
Text length of the indexed item.

WinQueryLboxItemTextLength - Parameters

hwndLbox ([HWND](#)) - input
Listbox handle.

index ([SHORT](#)) - input
Index of the item in the List Box.

sRetLen ([SHORT](#)) - returns
Text length of the indexed item.

WinQueryLboxItemTextLength - Remarks

This macro is defined as:

```
#define WinQueryLboxItemTextLength(hwndLbox, index) \

WinQueryMsgPos

WinQueryMsgPos - Syntax

This function returns the pointer position, in screen coordinates, when the last message obtained from the current message queue is posted.

```
#define INCL_WINMESSAGEGR /* Or use INCL_WIN, INCL_PM, */  
#include <os2.h>  
  
HAB      hab; /* Anchor-block handle. */  
PPOINTL  pptl; /* Pointer position in screen coordinates. */  
BOOL     rc; /* Success indicator. */  
  
rc = WinQueryMsgPos(hab, pptl);
```

WinQueryMsgPos Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinQueryMsgPos Parameter - pptl

pptl ([PPOINTL](#)) - output
Pointer position in screen coordinates.

WinQueryMsgPos Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinQueryMsgPos - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

pptl ([PPOINTL](#)) - output
Pointer position in screen coordinates.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinQueryMsgPos - Remarks

The pointer position is the same as that in the parameter of a [QMSG](#) structure.

To obtain the current position of the pointer, use the [WinQueryPointerPos](#) function.

WinQueryMsgTime

WinQueryMsgTime - Syntax

This function returns the message time for the last message retrieved by the [WinGetMsg](#) or [WinPeekMsg](#) functions from the current message queue.

```
#define INCL_WINMESSAGEGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;      /* Anchor-block handle. */
ULONG    ulTime;    /* Time in milliseconds. */

ulTime = WinQueryMsgTime(hab);
```

WinQueryMsgTime Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinQueryMsgTime Return Value - ulTime

ulTime ([ULONG](#)) - returns
Time in milliseconds.

WinQueryMsgTime - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

ulTime ([ULONG](#)) - returns
Time in milliseconds.

WinQueryMsgTime - Remarks

The message time is the time the message is posted, measured in milliseconds, from the time the system is started. Its value is the same as that in the parameter of the [QMSG](#) structure.

To calculate time delays between messages, the time of the first message is subtracted from the time of the second message.

Time values do not always increase because the value is the number of milliseconds since the system was started, and the system accumulator for this count can wrap through zero.

The WinQueryObject function returns a handle to the given object.

```
#define INCL_WINWORKPLACE
#include <os2.h>

PSZ      pObjectID; /* The object ID of an existing object. */
HOBJECT  hObject;   /* MRESULT. */

hObject = WinQueryObject(pObjectID);
```

WinQueryObject Parameter - pObjectID

pObjectID (**PSZ**) - input

The object ID of an existing object.

The object ID of an existing object, for example <LOCATION_DESKTOP>, or alternatively the fully qualified filename of any file or directory.

WinQueryObject Return Value - hObject

hObject (**HOBJECT**) - returns
MRESULT.

Persistent object handle, or NULLHANDLE if the object does not exist or could not be awakened.

WinQueryObject - Parameters

pObjectID (**PSZ**) - input

The object ID of an existing object.

The object ID of an existing object, for example <LOCATION_DESKTOP>, or alternatively the fully qualified filename of any file or directory.

hObject (**HOBJECT**) - returns

MRESULT.

Persistent object handle, or NULLHANDLE if the object does not exist or could not be awakened.

WinQueryObject - Remarks

This function allows you to obtain the persistent object handle for any file object, by passing the fully qualified filename. Similarly any objects' handle can be retrieved if its object ID string is passed. Once a program has an object handle, it is able to change the objects state by using the [WinSetObjectData](#) function or delete the object using the [WinDestroyObject](#) function. Note that valid object ID strings must always start with the "<" character and be terminated by the ">" character, and are thus invalid file system names.

Using [HOBJECT](#) for .INI files or files in which an application uses a rename/save/delete sequence is not supported.

WinQueryObjectPath

WinQueryObjectPath - Syntax

This function is specific to OS/2 Version 3.0 or higher.

This function returns the directory specification of a given object handle.

```
#define INCL_WINWORKPLACE
#include <os2.h>
```

```
HOBJECT    hObject;      /* Object handle of the object whose file/directory specification is to be returned.
PSZ         pszPathname; /* Memory allocated by caller in which directory specification is written. */
ULONG      ulSize;       /* Number of bytes pointed to by pszPathname. */
BOOL        rc;          /* Success indicator. */

rc = WinQueryObjectPath(hObject, pszPathname,
                        ulSize);
```

WinQueryObjectPath Parameter - hObject

hObject (**HOBJECT**) - input
Object handle of the object whose file/directory specification is to be returned.

WinQueryObjectPath Parameter - pszPathname

pszPathname (**PSZ**) - output
Memory allocated by caller in which directory specification is written.

WinQueryObjectPath Parameter - ulSize

ulSize (**ULONG**) - input
Number of bytes pointed to by *pszPathname*.

WinQueryObjectPath Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinQueryObjectPath - Parameters

hObject ([HOBJECT](#)) - input
Object handle of the object whose file/directory specification is to be returned.

pszPathname ([PSZ](#)) - output
Memory allocated by caller in which directory specification is written.

ulSize ([ULONG](#)) - input
Number of bytes pointed to by *pszPathname*.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinQueryObjectPath - Remarks

This function is used to find the file/directory specification of a given object handle.

Using [HOBJECT](#) for .INI files or files in which an application uses a rename/save/delete sequence is not supported.

WinQueryObjectPath - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_PARAMETERS (0x1208)
An application parameter value is invalid for its converted PM type. For example: a 4-byte value outside the range -32 768 to +32 767 cannot be converted to a [SHORT](#), and a negative number cannot be converted to a [ULONG](#) or [USHORT](#).

WinQueryObjectPath - Example Code

This example finds the file/directory of the <WP_OS2SYS> object..

```
#define INCL_WINWORKPLACE
#include <os2.h>

HOBJECT hObject;
CHAR      szPath[CCHMAXPATH + 1];
BOOL      fSuccess;

hObject = WinQueryObject("<WP_OS2SYS>");
if (hObject != NULL)
{
    /* WinQueryObject was successful */

    fSuccess = WinQueryObjectPath(hObject, szPath, sizeof(szPath));
    if (fSuccess)
    {
        /* WinQueryObjectPath was successful */
    }
    else
    {
        /* WinQueryObjectPath failed */
    }
}
```

```
else
{
    /* WinQueryObject failed */
}
```

WinQueryObjectWindow

WinQueryObjectWindow - Syntax

This function returns the desktop object window handle.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwndDesktop; /* Desktop-window handle. */
HWND    hwndObject;  /* Object-window handle. */

hwndObject = WinQueryObjectWindow(hwndDesktop);
```

WinQueryObjectWindow Parameter - hwndDesktop

hwndDesktop ([HWND](#)) - input
Desktop-window handle.

HWND_DESKTOP
The desktop-window handle

Other
Specified desktop-window handle.

WinQueryObjectWindow Return Value - hwndObject

hwndObject ([HWND](#)) - returns
Object-window handle.

NULLHANDLE
Error occurred.

WinQueryObjectWindow - Parameters

hwndDesktop ([HWND](#)) - input
Desktop-window handle.

HWND_DESKTOP
The desktop-window handle
Other
Specified desktop-window handle.

hwndObject ([HWND](#)) - returns
Object-window handle.

NULLHANDLE
Error occurred.

WinQueryObjectWindow - Remarks

Any window created as a descendant of *hwndObject* is an object window.

WinQueryObjectWindow - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinQueryObjectWindow - Example Code

This example calls WinQueryObjectWindow to return the desktop object window handle. All windows created as descendants of this object window-as in the example-will be object windows.

```
#define INCL_WINWINDOWMGR      /* Window Manager Functions */
#include <os2.h>

HWND    hwndObject;           /* desktop object window */
HWND    hwndObject1;          /* descendant object window */
USHORT   WindowId;
hwndObject = WinQueryObjectWindow(HWND_DESKTOP);

/* create object window */
hwndObject1 = WinCreateWindow(hwndObject, /* parent window */
                              "NewClass", /* class name */
                              "new button", /* window text */
                              WS_VISIBLE, /* window style */
                              0, 0, /* position (x,y) */
                              200, 100, /* size (width,height) */
                              0L, /* owner window */
                              HWND_TOP, /* sibling window */
                              WindowId, /* window id */
                              NULL, /* control data */
                              NULL); /* presentation parms */
```

WinQueryPointer

WinQueryPointer - Syntax

This function returns the pointer handle for *hwndDeskTop*.

```
#define INCL_WINPOINTERS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwndDesktop; /* Desktop-window handle. */
HPOINTER  hptrPointer; /* Pointer handle. */

hptrPointer = WinQueryPointer(hwndDesktop);
```

WinQueryPointer Parameter - hwndDesktop

hwndDesktop (**HWND**) - input
Desktop-window handle.

HWND_DESKTOP	The desktop-window handle
Other	Specified desktop-window handle.

WinQueryPointer Return Value - hptrPointer

hptrPointer (**HPOINTER**) - returns
Pointer handle.

NULLHANDLE	Error occurred.
------------	-----------------

WinQueryPointer - Parameters

hwndDesktop (**HWND**) - input
Desktop-window handle.

HWND_DESKTOP	The desktop-window handle
Other	Specified desktop-window handle.

hptrPointer (**HPOINTER**) - returns
Pointer handle.

NULLHANDLE	Error occurred.
------------	-----------------

WinQueryPointer - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinQueryPointer - Related Functions

WinQueryPointerInfo

WinQueryPointerInfo - Syntax

This function returns pointer information.

```
#define INCL_WINPOINTERS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HPOINTER      hptr;          /* Pointer handle. */
PPOINTERINFO  pptriPointerInfo; /* Pointer-information structure. */
BOOL          rc;            /* Success indicator. */

rc = WinQueryPointerInfo(hptr, pptriPointerInfo);
```

WinQueryPointerInfo Parameter - hptr

hptr (**HPOINTER**) - input
Pointer handle.

WinQueryPointerInfo Parameter - pptriPointerInfo

pptriPointerInfo (**PPOINTERINFO**) - output
Pointer-information structure.

WinQueryPointerInfo Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinQueryPointerInfo - Parameters

hptr ([HPOINTER](#)) - input
Pointer handle.

pptriPointerInfo ([PPOINTERINFO](#)) - output
Pointer-information structure.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinQueryPointerInfo - Remarks

The pointer information structure contains information such as the bit-map handle of the pointer and action point coordinates. The values returned for the parameters are in units relative to the size of the system icon or system pointer.

For example, if the application creates a pointer out of a bit map xWide units wide and positions the x-coordinate of the pointer's action point at xHot, then this function will return the value of the as:

```
xHotspot = (xHot * SystemPointerWidth) / xWide
```

where SystemPointerWidth can be obtained by using the [WinQuerySysValue](#) function.

WinQueryPointerInfo - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HPTR (0x101B)
An invalid pointer handle was specified.

WinQueryPointerInfo - Example Code

This example uses the WinQueryPointerInfo call to obtain the bit-map handle of the color bit map.

```
#define INCL_WINPOINTERS
#define INCL_WINDESKTOP
#include <OS2.H>

HAB      hab;
HPOINTER hpointer;
POINTERINFO pointerinfo;
HBITMAP  hbm;          /* Bit-map handle of color bit map */

hpointer = WinQueryPointer(HWND_DESKTOP);

WinQueryPointerInfo(hpointer,
                    &pointerinfo);

hbm = pointerinfo.hbmColor;
```

WinQueryPointerPos

WinQueryPointerPos - Syntax

This function returns the pointer position.

```
#define INCL_WINPOINTERS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwndDeskTop; /* Desktop-window handle. */
PPOINTL   pptlPoint;   /* Pointer position in screen coordinates. */
BOOL      rc;          /* Pointer position returned indicator. */
```

```
rc = WinQueryPointerPos(hwndDeskTop, pptlPoint);
```

WinQueryPointerPos Parameter - hwndDeskTop

hwndDeskTop ([HWND](#)) - input
Desktop-window handle.

HWND_DESKTOP	The desktop-window handle
Other	Specified desktop-window handle.

WinQueryPointerPos Parameter - pptlPoint

pptlPoint ([PPOINTL](#)) - output
Pointer position in screen coordinates.

WinQueryPointerPos Return Value - rc

rc ([BOOL](#)) - returns
Pointer position returned indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinQueryPointerPos - Parameters

hwndDeskTop ([HWND](#)) - input
Desktop-window handle.

HWND_DESKTOP	The desktop-window handle
Other	Specified desktop-window handle.

pptlPoint ([PPOINTL](#)) - output
Pointer position in screen coordinates.

rc ([BOOL](#)) - returns
Pointer position returned indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinQueryPointerPos - Remarks

The [WinQueryMsgPos](#) is used to get the pointer position of the last message obtained by means of the [WinGetMsg](#) or [WinPeekMsg](#) functions.

WinQueryPointerPos - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinQueryPresParam

WinQueryPresParam - Syntax

This function queries the values of presentation parameters for a window.

```

#define INCL_WINSYS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwnd;          /* Window handle whose presentation is to be queried. */
ULONG     idAttrType1;   /* First presentation parameter to retrieve. */
ULONG     idAttrType2;   /* Second presentation parameter to retrieve. */
PULONG    pidAttrTypeFound; /* Presentation parameter attribute found. */
ULONG     cbAttrValueLen; /* Size of the buffer pointed to by the pAttrValue parameter. */
PPVOID    pAttrValue;    /* Attribute value. */
ULONG     flOptions;      /* Options controlling the query. */
ULONG     cbRetLen;       /* Length of presentation parameter value. passed back. */

cbRetLen = WinQueryPresParam(hwnd, idAttrType1,
                             idAttrType2, pidAttrTypeFound,
                             cbAttrValueLen, pAttrValue, flOptions);

```

WinQueryPresParam Parameter - hwnd

hwnd (HWND) - input
Window handle whose presentation is to be queried.

WinQueryPresParam Parameter - idAttrType1

idAttrType1 (ULONG) - input
First presentation parameter to retrieve.

This identifies the first presentation parameter attribute to be queried. It can be zero to reference no presentation parameter attribute.

WinQueryPresParam Parameter - idAttrType2

idAttrType2 (ULONG) - input
Second presentation parameter to retrieve.

This identifies the second presentation parameter attribute to be queried. It can be zero to reference no presentation parameter attribute.

WinQueryPresParam Parameter - pidAttrTypeFound

pidAttrTypeFound (PULONG) - in/out
Presentation parameter attribute found.

This identifies which of the presentation parameter attributes *idAttrType1* and *idAttrType2* has been found. This parameter can be passed as NULL (if, for example, only one attribute is being queried).

WinQueryPresParam Parameter - cbAttrValueLen

cbAttrValueLen (ULONG) - input
Size of the buffer pointed to by the *pAttrValue* parameter.

WinQueryPresParam Parameter - pAttrValue

pAttrValue (PPVOID) - output
Attribute value.

The value of the presentation parameter attribute found.

WinQueryPresParam Parameter - flOptions

flOptions (ULONG) - input

Options controlling the query.

Any of the following values can be ORed together:

QPF_NOINHERIT

For the purposes of this query, presentation parameters are not inherited from the owners of the window specified by *hwnd*. If not specified (default), presentation parameters are inherited.

QPF_ID1COLORINDEX

idAttrType1 refers to a color index presentation parameter attribute, the value of which, if found, is to be converted to RGB before being passed back in *pAttrValue*.

QPF_ID2COLORINDEX

idAttrType2 refers to a color index presentation parameter attribute, the value of which, if found, is to be converted to RGB before being passed back in *pAttrValue*.

QPF_PURERGBCOLOR

Specifies that either or both of *idAttrType1* and *idAttrType2* reference RGB color, and that these colors must be pure. This is necessary when specifying text foreground and background colors. This is applied after QPF_ID1COLORINDEX and QPF_ID2COLORINDEX.

WinQueryPresParam Return Value - cbRetLen

cbRetLen (ULONG) - returns

Length of presentation parameter value. passed back.

Zero

Presentation parameter not found or error occurred

Other

Length of presentation parameter value passed back in *pAttrValue*.

WinQueryPresParam - Parameters

hwnd (HWND) - input

Window handle whose presentation is to be queried.

idAttrType1 (ULONG) - input

First presentation parameter to retrieve.

This identifies the first presentation parameter attribute to be queried. It can be zero to reference no presentation parameter attribute.

idAttrType2 (ULONG) - input

Second presentation parameter to retrieve.

This identifies the second presentation parameter attribute to be queried. It can be zero to reference no presentation parameter attribute.

pidAttrTypeFound ([PULONG](#)) - in/out

Presentation parameter attribute found.

This identifies which of the presentation parameter attributes *idAttrType1* and *idAttrType2* has been found. This parameter can be passed as NULL (if, for example, only one attribute is being queried).

cbAttrValueLen ([ULONG](#)) - input

Size of the buffer pointed to by the *pAttrValue* parameter.

pAttrValue ([PPVOID](#)) - output

Attribute value.

The value of the presentation parameter attribute found.

flOptions ([ULONG](#)) - input

Options controlling the query.

Any of the following values can be ORed together:

QPF_NOINHERIT

For the purposes of this query, presentation parameters are not inherited from the owners of the window specified by *hwnd*. If not specified (default), presentation parameters are inherited.

QPF_ID1COLORINDEX

idAttrType1 refers to a color index presentation parameter attribute, the value of which, if found, is to be converted to RGB before being passed back in *pAttrValue*.

QPF_ID2COLORINDEX

idAttrType2 refers to a color index presentation parameter attribute, the value of which, if found, is to be converted to RGB before being passed back in *pAttrValue*.

QPF_PURERGBCOLOR

Specifies that either or both of *idAttrType1* and *idAttrType2* reference RGB color, and that these colors must be pure. This is necessary when specifying text foreground and background colors. This is applied after QPF_ID1COLORINDEX and QPF_ID2COLORINDEX.

cbRetLen ([ULONG](#)) - returns

Length of presentation parameter value. passed back.

Zero

Presentation parameter not found or error occurred

Other

Length of presentation parameter value passed back in *pAttrValue*.

WinQueryPresParam - Remarks

Two presentation parameter attribute identities can be passed, and both will be searched for along the chain of owners of the window *hwnd* (subject to QPF_NOINHERIT). The first one found satisfies the query. If both *idAttrType1* and *idAttrType2* are present for the same window, *idAttrType1* takes precedence.

If the presentation parameter attribute value is too long to fit in the *pAttrValue* buffer provided, it is truncated, and the number of bytes copied is returned in *cbRetLen*. (See also [WinSetPresParam](#) and [WinRemovePresParam](#)).

WinQueryPresParam - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)

An invalid window handle was specified.

WinQueryQueueInfo

WinQueryQueueInfo - Syntax

This function returns the information for the specified queue.

```
#define INCL_WINMESSAGEGR /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HMQ      hmq;          /* Queue handle. */
PMQINFO  pmqiMqinfo;   /* Message queue information structure to contain the queue information. */
ULONG    cbCopied;     /* Size of message queue information structure that is provided (in bytes). */
BOOL     rc;           /* Success indicator. */

rc = WinQueryQueueInfo(hmq, pmqiMqinfo, cbCopied);
```

WinQueryQueueInfo Parameter - hmq

hmq (**HMQ**) - input
Queue handle.

It must be created by a previous call to [WinCreateMsgQueue](#) or HMQ_CURRENT.

WinQueryQueueInfo Parameter - pmqiMqinfo

pmqiMqinfo (**PMQINFO**) - output
Message queue information structure to contain the queue information.

WinQueryQueueInfo Parameter - cbCopied

cbCopied (**ULONG**) - input
Size of message queue information structure that is provided (in bytes).

Specifies the maximum number of bytes to be copied into the *pmqiMqinfo* parameter. This should be the size of an **MQINFO** structure.

WinQueryQueueInfo Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinQueryQueueInfo - Parameters

hmq ([HMQ](#)) - input
Queue handle.

It must be created by a previous call to [WinCreateMsgQueue](#) or HMQ_CURRENT.

pmqiMqinfo ([PMQINFO](#)) - output
Message queue information structure to contain the queue information.

cbCopied ([ULONG](#)) - input
Size of message queue information structure that is provided (in bytes).

Specifies the maximum number of bytes to be copied into the *pmqiMqinfo* parameter. This should be the size of an [MQINFO](#) structure.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinQueryQueueInfo - Example Code

This example retrieves the process identity from a queue by passing the queue handle to WinQueryQueueInfo.

```
#define INCL_WINMESSAGEMGR
#include <OS2.H>

HMQ      hmq;
MQINFO   mqinfo;
PID       pid;

WinQueryQueueInfo(hmq,
                  &mqinfo,
                  sizeof(MQINFO));

pid = mqinfo.pid;
```

WinQueryQueueStatus

WinQueryQueueStatus - Syntax

This function returns a code indicating the status of the message queue associated with the caller.

```
#define INCL_WINMESSAGEMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwndDesktop; /* Desktop-window handle. */
ULONG     flStatus;     /* Status information. */

flStatus = WinQueryQueueStatus(hwndDesktop);
```

WinQueryQueueStatus Parameter - hwndDesktop

hwndDesktop ([HWND](#)) - input
Desktop-window handle.

[HWND_DESKTOP](#)
The desktop-window handle

Other
Desktop-window handle returned by [WinQueryDesktopWindow](#).

WinQueryQueueStatus Return Value - flStatus

flStatus ([ULONG](#)) - returns
Status information.

Summary

- Summary of message types existing on the queue.
- This field contains a combination of the following values:
- QS_KEY**
An input event (keyboard or journaling) has caused a [WM_CHAR](#) message to be placed in the queue.
 - QS_MOUSE**
An input event has caused a [WM_MOUSEMOVE](#), [WM_BUTTON1UP](#), [WM_BUTTON1DOWN](#), [WM_BUTTON1DBLCLK](#), [WM_BUTTON2UP](#), [WM_BUTTON2DOWN](#), [WM_BUTTON2DBLCLK](#), [WM_BUTTON3UP](#), [WM_BUTTON3DOWN](#), or [WM_BUTTON3DBLCLK](#) message to be placed in the queue.
 - QS_MOUSEBUTTON**
An input event has caused a [WM_BUTTON1UP](#), [WM_BUTTON1DOWN](#), [WM_BUTTON1DBLCLK](#), [WM_BUTTON2UP](#), [WM_BUTTON2DOWN](#), [WM_BUTTON2DBLCLK](#), [WM_BUTTON3UP](#), [WM_BUTTON3DOWN](#), or [WM_BUTTON3DBLCLK](#) message to be placed in the queue.
 - QS_MOUSEMOVE**
An input event has caused a [WM_MOUSEMOVE](#) message to be placed in the queue.
 - QS_TIMER**
A timer event has caused a [WM_TIMER](#) message to be placed in the queue.
 - QS_PAINT**
A [WM_PAINT](#) message is available.
 - QS_SEM1**
A [WM_SEM1](#) message is available.
 - QS_SEM2**
A [WM_SEM2](#) message is available.
 - QS_SEM3**
A [WM_SEM3](#) message is available.
 - QS_SEM4**
A [WM_SEM4](#) message is available.

QS_POSTMSG	A message has been posted to the queue. Note that this message is probably not one of the messages listed above, but could be a WM_CHAR , WM_MOUSEMOVE or similar message if an application has posted one of these. In this case, the corresponding input status flag (QS_KEY, QS_MOUSE, and so on) is not set.
QS_SENDMSG	A message has been sent by another application to a window associated with the current queue.

Added

Message type additions.

Message types added to the queue since the last use of this function. The value of this field is a subset of the *Summary* field.

WinQueryQueueStatus - Parameters

hwndDesktop ([HWND](#)) - input
Desktop-window handle.

HWND_DESKTOP

The desktop-window handle

Other

Desktop-window handle returned by [WinQueryDesktopWindow](#).

flStatus ([ULONG](#)) - returns
Status information.

Summary

Summary of message types existing on the queue.

This field contains a combination of the following values:

QS_KEY	An input event (keyboard or journaling) has caused a WM_CHAR message to be placed in the queue.
QS_MOUSE	An input event has caused a WM_MOUSEMOVE , WM_BUTTON1UP , WM_BUTTON1DOWN , WM_BUTTON1DBLCLK , WM_BUTTON2UP , WM_BUTTON2DOWN , WM_BUTTON2DBLCLK , WM_BUTTON3UP , WM_BUTTON3DOWN , or WM_BUTTON3DBLCLK message to be placed in the queue.
QS_MOUSEBUTTON	An input event has caused a WM_BUTTON1UP , WM_BUTTON1DOWN , WM_BUTTON1DBLCLK , WM_BUTTON2UP , WM_BUTTON2DOWN , WM_BUTTON2DBLCLK , WM_BUTTON3UP , WM_BUTTON3DOWN , or WM_BUTTON3DBLCLK message to be placed in the queue.
QS_MOUSEMOVE	An input event has caused a WM_MOUSEMOVE message to be placed in the queue.
QS_TIMER	A timer event has caused a WM_TIMER message to be placed in the queue.
QS_PAINT	A WM_PAINT message is available.
QS_SEM1	A WM_SEM1 message is available.
QS_SEM2	A WM_SEM2 message is available.

QS_SEM3	A WM_SEM3 message is available.
QS_SEM4	A WM_SEM4 message is available.
QS_POSTMSG	A message has been posted to the queue. Note that this message is probably not one of the messages listed above, but could be a WM_CHAR , WM_MOUSEMOVE or similar message if an application has posted one of these. In this case, the corresponding input status flag (QS_KEY, QS_MOUSE, and so on) is not set.
QS_SENDMSG	A message has been sent by another application to a window associated with the current queue.

Added

Message type additions.

Message types added to the queue since the last use of this function. The value of this field is a subset of the *Summary* field.

WinQueryQueueStatus - Remarks

This function is an efficient method for determining whether input is available for processing by the [WinGetMsg](#) or [WinPeekMsg](#) functions.

WinQuerySessionTitle

WinQuerySessionTitle - Syntax

This function obtains the title under which a specified application is started, or is added to the Window List.

```
#define INCL_WINSWITCHLIST /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
ULONG    ulSession;    /* Session identity of application whose title is requested. */
PSZ      pszTitle;     /* Window List title. */
ULONG    ulTitlelen;   /* Maximum length of data returnable, in bytes. */
ULONG    rc;           /* Return code. */

rc = WinQuerySessionTitle(hab, ulSession,
                          pszTitle, ulTitlelen);
```

WinQuerySessionTitle Parameter - hab

hab (**HAB**) - input
Anchor-block handle.

WinQuerySessionTitle Parameter - ulSession

ulSession (**ULONG**) - input
Session identity of application whose title is requested.

- | | |
|-------|--|
| 0 | Use the session identity of the caller |
| Other | Use the specified session identity. |

WinQuerySessionTitle Parameter - pszTitle

pszTitle (**PSZ**) - output
Window List title.

This is the title of the application with a process identity, if the application is present in the Window List.

WinQuerySessionTitle Parameter - ulTitlelen

ulTitlelen (**ULONG**) - input
Maximum length of data returnable, in bytes.

If the *pszTitle* parameter is longer than this value, the title is truncated. However, the terminating null character is left at the end of the string. The maximum number of title characters copied is (*ulTitlelen*-1).

WinQuerySessionTitle Return Value - rc

rc ([ULONG](#)) - returns
Return code.

0	Successful completion
Other	Error occurred.

WinQuerySessionTitle - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

ulSession ([ULONG](#)) - input
Session identity of application whose title is requested.

0	Use the session identity of the caller
Other	Use the specified session identity.

pszTitle ([PSZ](#)) - output
Window List title.

This is the title of the application with a process identity, if the application is present in the Window List.

ulTitlelen ([ULONG](#)) - input
Maximum length of data returnable, in bytes.

If the *pszTitle* parameter is longer than this value, the title is truncated. However, the terminating null character is left at the end of the string. The maximum number of title characters copied is (*ulTitlelen*-1).

rc ([ULONG](#)) - returns
Return code.

0	Successful completion
Other	Error occurred.

WinQuerySessionTitle - Remarks

This function is useful when an application uses the same name in its window title (and in its entry in the Window List) as the end user invokes to start the application. This provides a visual link for the end user.

If this function is used after a Window List entry is created for the application, the title in the Window List entry is obtained. (See also [WinQueryTaskTitle](#).)

WinQuerySessionTitle - Example Code

This example calls WinQuerySessionTitle to retrieve the application's title, and then sets the title bar of the frame window to that title.

```
#define INCL_WINMESSAGEGR
#define INCL_WINWINDOWMGR
#include <OS2.H>

HAB hab;
HWND hwndFrame, hwndClient;
CHAR szTitle[MAXNAMEL + 1];

WinQuerySessionTitle(hab,
                    0,
                    szTitle,
                    sizeof(szTitle));

hwndFrame = WinQueryWindow(hwndClient,
                          QW_PARENT); /* get handle of parent, */
                                      /* which is frame window. */
WinSetWindowText(hwndFrame, szTitle);
```

WinQuerySwitchEntry

WinQuerySwitchEntry - Syntax

This function obtains a copy of the Window List data for a specific application.

```
#define INCL_WINSWITCHLIST /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HSWITCH      hswitchSwitch; /* Handle to the Window List entry. */
PSWCNTRL     pswctlSwitchData; /* Switch control data. */
ULONG        rc; /* Return code. */

rc = WinQuerySwitchEntry(hswitchSwitch, pswctlSwitchData);
```

WinQuerySwitchEntry Parameter - hswitchSwitch

hswitchSwitch ([HSWITCH](#)) - input
Handle to the Window List entry.

This can be obtained using the [WinQuerySwitchHandle](#) function.

WinQuerySwitchEntry Parameter - pswctlSwitchData

pswctlSwitchData ([PSWCNTRL](#)) - output
Switch control data.

Contains information about the specified Window List entry. The field contains the program handle used to start the program.

WinQuerySwitchEntry Return Value - rc

rc ([ULONG](#)) - returns
Return code.

0	Successful completion
Other	Error occurred.

WinQuerySwitchEntry - Parameters

hswitchSwitch ([HSWITCH](#)) - input
Handle to the Window List entry.

This can be obtained using the [WinQuerySwitchHandle](#) function.

pswctlSwitchData ([PSWCNTRL](#)) - output
Switch control data.

Contains information about the specified Window List entry. The field contains the program handle used to start the program.

rc ([ULONG](#)) - returns
Return code.

0	Successful completion
Other	Error occurred.

WinQuerySwitchEntry - Remarks

This function is available to PM and non-PM applications.

WinQuerySwitchHandle

WinQuerySwitchHandle - Syntax

This function obtains the Window List handle belonging to a window.

```
#define INCL_WINSWITCHLIST /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwnd;          /* Window handle of an application. */
PID       idProcess;     /* Process identity of the application. */
HSWITCH   hswitchSwitch; /* Switch list handle for the specified application. */

hswitchSwitch = WinQuerySwitchHandle(hwnd,
                                     idProcess);
```

WinQuerySwitchHandle Parameter - hwnd

hwnd (**HWND**) - input

Window handle of an application.

Window handle of an application running in the OS/2 session for which the Window List handle is required.

NULLHANDLE

Application is not an OS/2 application

Other

Window handle of an application.

WinQuerySwitchHandle Parameter - idProcess

idProcess (**PID**) - input
Process identity of the application.

WinQuerySwitchHandle Return Value - hswitchSwitch

hswitchSwitch (**HSWITCH**) - returns
Switch list handle for the specified application.

NULLHANDLE	Application is not in the switch list, or an error occurred
Other	Switch list handle.

WinQuerySwitchHandle - Parameters

hwnd (**HWND**) - input
Window handle of an application.

Window handle of an application running in the OS/2 session for which the Window List handle is required.

NULLHANDLE	Application is not an OS/2 application
Other	Window handle of an application.

idProcess (**PID**) - input
Process identity of the application.

hswitchSwitch (**HSWITCH**) - returns
Switch list handle for the specified application.

NULLHANDLE	Application is not in the switch list, or an error occurred
Other	Switch list handle.

WinQuerySwitchHandle - Remarks

If both a window handle and a process identity are supplied, they must be consistent.

If the window handle is NULL and the process identity supplied cannot be found in the switch list then the switch handle returned is the handle for the most proximal ancestor process. Once the switch list handle is obtained, it may be used in various other calls to manipulate the switch list entry or the program which it references.

WinQuerySwitchList

WinQuerySwitchList - Syntax

This function obtains information about the entries in the Window List.

```
#define INCL_WINSWITCHLIST /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
PSWBLOCK pswblkBlock;  /* Switch entries block. */
ULONG    ulLength;     /* Maximum length of data returnable in bytes. */
ULONG    ulCount;      /* Total number of switch list entries present in the system. */

ulCount = WinQuerySwitchList(hab, pswblkBlock,
                             ulLength);
```

WinQuerySwitchList Parameter - hab

hab (**HAB**) - input
Anchor-block handle.

WinQuerySwitchList Parameter - pswblkBlock

pswblkBlock (**PSWBLOCK**) - in/out
Switch entries block.

Contains a description of all the entries in the current switch list. This is held in a **SWBLOCK** structure, which has a count of the number of switch list entries, plus a record for each entry containing data such as the process and session identities, the icon handle, and the window handle for the running program.

NULL
No information returned; the return parameter however contains the total number of switch list entries.

Other
Switch entries block.

WinQuerySwitchList Parameter - ulLength

ulLength (**ULONG**) - input
Maximum length of data returnable in bytes.

This is the maximum length in bytes of the data that can be returned in the *pswblkBlock* parameter.

0
No information returned, however the return parameter contains the total number of switch list entries.

Other

Maximum length of data returnable.

WinQuerySwitchList Return Value - ulCount

ulCount ([ULONG](#)) - returns

Total number of switch list entries present in the system.

0

Error occurred

Other

Total number of switch list entries present in the system.

WinQuerySwitchList - Parameters

hab ([HAB](#)) - input

Anchor-block handle.

pswblkBlock ([PSWBLOCK](#)) - in/out

Switch entries block.

Contains a description of all the entries in the current switch list. This is held in a [SWBLOCK](#) structure, which has a count of the number of switch list entries, plus a record for each entry containing data such as the process and session identities, the icon handle, and the window handle for the running program.

NULL

No information returned; the return parameter however contains the total number of switch list entries.

Other

Switch entries block.

ulLength ([ULONG](#)) - input

Maximum length of data returnable in bytes.

This is the maximum length in bytes of the data that can be returned in the *pswblkBlock* parameter.

0

No information returned, however the return parameter contains the total number of switch list entries.

Other

Maximum length of data returnable.

ulCount ([ULONG](#)) - returns

Total number of switch list entries present in the system.

0

Error occurred

Other

Total number of switch list entries present in the system.

WinQuerySwitchList - Remarks

It is possible to obtain information about all the programs currently executing in a single operation, with one array entry for each program.

WinQuerySwitchList - Example Code

This example determines the number of items in the Task List, allocates memory for the required buffer, and then calls WinQuerySwitchList again to fill the buffer with the information about each item in the Task List.

```
#define INCL_DOSMEMMGR
#define INCL_DOSERRORS
#define INCL_WINSWITCHLIST /* Or INCL_WIN, INCL_PM */
#include <OS2.H>

#define MEMPOOL 40000 /* Size of local memory pool area */

HAB      hab      = NULLHANDLE;
HWND     hwndFrame = NULLHANDLE;
ULONG    cbItems   = 0,          /* Number of items in list */
          ulBufSize = 0;          /* Size of buffer for information */
PVOID    pvBase    = NULL;       /* Pointer to local memory pool */
PSWBLOCK pswblk    = NULL;       /* Pointer to information returned */
APIRET   rc        = NO_ERROR;   /* Return code from Dos APIs */

/* Allocate a large block of memory (uncommitted) and make
   it available for suballocation. This allows the system
   to commit memory only when it is actually needed. */

rc = DosAllocMem( &pvBase, MEMPOOL, PAG_READ | PAG_WRITE );
rc = DosSubSetMem( pvBase, DOSSUB_INIT | DOSSUB_SPARSE_OBJ, MEMPOOL );

/* Determine the number of items in the list and calculate
   the size of the buffer needed. */

cbItems = WinQuerySwitchList(hab, NULL, 0);
ulBufSize = (cbItems * sizeof(SWENTRY)) + sizeof(HSWITCH);

/* Allocate the buffer from our memory pool */

rc = DosSubAllocMem( pvBase, (PVOID) &pswblk, ulBufSize);

/* Call WinQuerySwitchList again to fill our buffer with information */

cbItems = WinQuerySwitchList(hab, pswblk, ulBufSize);

WinQuerySysColor

WinQuerySysColor - Syntax

This function returns the system color.

```
#define INCL_WINSYS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwndDesktop; /* Desktop-window handle. */
LONG    clr;          /* System color-index value. */
LONG    lReserved;    /* Reserved value, must be 0. */
LONG    lRgbColor;    /* RGB value. */

lRgbColor = WinQuerySysColor(hwndDesktop,
                             clr, lReserved);
```

WinQuerySysColor Parameter - hwndDesktop

hwndDesktop (**HWND**) - input
Desktop-window handle.

HWND_DESKTOP	The desktop-window handle
Other	Specified desktop-window handle.

WinQuerySysColor Parameter - clr

clr (**LONG**) - input
System color-index value.

Must be one of the SYSCLR_* index values.

WinQuerySysColor Parameter - IReserved

IReserved ([LONG](#)) - input
Reserved value, must be 0.

WinQuerySysColor Return Value - IRgbColor

IRgbColor ([LONG](#)) - returns
RGB value.

i1.RGB (red-green-blue) RGB value corresponding to the *clr* parameter.

WinQuerySysColor - Parameters

hwndDesktop ([HWND](#)) - input
Desktop-window handle.

 HWND_DESKTOP The desktop-window handle
 Other Specified desktop-window handle.

clr ([LONG](#)) - input
System color-index value.

 Must be one of the SYSCLR_* index values.

IReserved ([LONG](#)) - input
Reserved value, must be 0.

IRgbColor ([LONG](#)) - returns
RGB value.

i1.RGB (red-green-blue) RGB value corresponding to the *clr* parameter.

WinQuerySysColor - Remarks

This function returns the color value that corresponds to the specified color index of the specified color palette.

The following are the available SYSCLR_* values:

System Color Index	Default Color	Default RGB Values
SYSCLR_ACTIVEBORDER	Pale yellow	255 255 128

SYSCLR_ACTIVETITLE	Teal	64	128	128
SYSCLR_ACTIVETITLETEXT	White	255	255	255

WinQuerySysColor - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

PMERR_PARAMETER_OUT_OF_RANGE (0x1003)
The value of a parameter was not within the defined valid range for that parameter.

WinQuerySysColor - Example Code

This example uses the WinQuerySysColor to find the RGB index of the system push button, SYSCLR_BUTTONDEFAULT.

```
#define INCL_WINSYS
#define INCL_WINDESKTOP
#include <OS2.H>

HAB hab;
LONG lRgbColor;

lRgbColor = WinQuerySysColor(HWND_DESKTOP,
                             SYSCLR_BUTTONDEFAULT,
                             0L);
```

WinQuerySysModalWindow

WinQuerySysModalWindow - Syntax

This function returns the current system modal window.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwndDesktop; /* Desktop-window handle. */
HWND    hwndSysModal; /* Handle of system modal window. */

hwndSysModal = WinQuerySysModalWindow(hwndDesktop);
```

WinQuerySysModalWindow Parameter - hwndDesktop

hwndDesktop ([HWND](#)) - input
Desktop-window handle.

HWND_DESKTOP	The desktop-window handle
Other	Specified desktop-window handle.

WinQuerySysModalWindow Return Value - hwndSysModal

hwndSysModal ([HWND](#)) - returns
Handle of system modal window.

NULLHANDLE	No system modal window
Other	Handle of system modal window.

WinQuerySysModalWindow - Parameters

hwndDesktop ([HWND](#)) - input

Desktop-window handle.

HWND_DESKTOP

The desktop-window handle

Other

Specified desktop-window handle.

hwndSysModal ([HWND](#)) - returns

Handle of system modal window.

NULLHANDLE

No system modal window

Other

Handle of system modal window.

WinQuerySysModalWindow - Remarks

For a full description of the operation of the system modal window, see the [WinSetSysModalWindow](#) function.

WinQuerySysModalWindow - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)

An invalid window handle was specified.

WinQuerySysModalWindow - Example Code

This example uses the WinQuerySysModalWindow to find the handle of the system modal window.

```
#define INCL_WINWINDOWMGR
#include <OS2.H>

HAB hab;
HWND hwndDeskTop, hwndSysModal;
LONG lRgbColor;

/* Input processing can enter a "system modal" state. In */
/* this state, all pointing device and keyboard input */
/* is directed to a special window, known as the */
/* system-modal window. Typically, this will be a dialog */
/* window requiring input. */
```

```
hwndSysModal = WinQuerySysModalWindow(hwndDesktop);
```

WinQuerySysPointer

WinQuerySysPointer - Syntax

This function returns the system-pointer handle.

```
#define INCL_WINPOINTERS /* Or use INCL_WIN, INCL_PM, */  
#include <os2.h>  
  
HWND      hwndDesktop; /* Desktop-window handle. */  
LONG      lIdentifier; /* System-pointer identifier. */  
BOOL      fCopy;       /* Copy indicator. */  
HPOINTER  hptrPointer; /* Pointer handle. */  
  
hptrPointer = WinQuerySysPointer(hwndDesktop,  
                                lIdentifier, fCopy);
```

WinQuerySysPointer Parameter - hwndDesktop

hwndDesktop ([HWND](#)) - input
Desktop-window handle.

WinQuerySysPointer Parameter - lIdentifier

Identifier (LONG) - input
System-pointer identifier.

SPTR_ARROW	Arrow pointer
SPTR_TEXT	Text I-beam pointer
SPTR_WAIT	Hourglass pointer
SPTR_SIZE	Size pointer
SPTR_MOVE	Move pointer
SPTR_SIZENWSE	Downward-sloping, double-headed arrow pointer
SPTR_SIZENESW	Upward-sloping, double-headed arrow pointer
SPTR_SIZewe	Horizontal, double-headed arrow pointer
SPTR_SIZENS	Vertical, double-headed arrow pointer
SPTR_APPICON	Standard application icon pointer
SPTR_ICONINFORMATION	Information icon pointer
SPTR_ICONQUESTION	Question mark icon pointer
SPTR_ICONERROR	Exclamation mark icon pointer
SPTR_ICONWARNING	Warning icon pointer
SPTR_ILLEGAL	Illegal operation icon pointer
SPTR_FILE	Single file icon pointer
SPTR_MULTIFILE	Multiple files icon pointer
SPTR_FOLDER	Folder icon pointer
SPTR_PROGRAM	Application program icon pointer

WinQuerySysPointer Parameter - fCopy

fCopy (BOOL) - input
Copy indicator.

TRUE	Create a copy of the default system pointer and return its handle. Specify this value if the system pointer is to be modified. The application should destroy the copy of the pointer created. This can be done by using the WinDestroyPointer function.
FALSE	Return the handle of the current system pointer.

WinQuerySysPointer Return Value - hptrPointer

hpPtrPointer (**HPOINTER**) - returns
Pointer handle.

WinQuerySysPointer - Parameters

hwndDeskTop (**HWND**) - input
Desktop-window handle.

lIdentifier (**LONG**) - input
System-pointer identifier.

- SPTR_ARROW
Arrow pointer
- SPTR_TEXT
Text I-beam pointer
- SPTR_WAIT
Hourglass pointer
- SPTR_SIZE
Size pointer
- SPTR_MOVE
Move pointer
- SPTR_SIZENWSE
Downward-sloping, double-headed arrow pointer
- SPTR_SIZENESW
Upward-sloping, double-headed arrow pointer
- SPTR_SIZewe
Horizontal, double-headed arrow pointer
- SPTR_SIZENS
Vertical, double-headed arrow pointer
- SPTR_APPICON
Standard application icon pointer
- SPTR_ICONINFORMATION
Information icon pointer
- SPTR_ICONQUESTION
Question mark icon pointer
- SPTR_ICONERROR
Exclamation mark icon pointer
- SPTR_ICONWARNING
Warning icon pointer
- SPTR_ILLEGAL
Illegal operation icon pointer
- SPTR_FILE
Single file icon pointer
- SPTR_MULTIFILE
Multiple files icon pointer
- SPTR_FOLDER
Folder icon pointer
- SPTR_PROGRAM
Application program icon pointer

fCopy (**BOOL**) - input
Copy indicator.

- TRUE
Create a copy of the default system pointer and return its handle. Specify this value if the system pointer is to be modified. The application should destroy the copy of the pointer created. This can be done by using the WinDestroyPointer function.
- FALSE
Return the handle of the current system pointer.

hpPtrPointer (**HPOINTER**) - returns
Pointer handle.

WinQuerySysPointer - Remarks

Take care when using the pointer bit-map handles returned by the [WinQueryPointerInfo](#) function in the [POINTERINFO](#) structure. If the handle is a system-pointer handle, or is returned by the [WinQueryPointerInfo](#) function, it is possible that another application is also accessing the bit-map handle. If this is so, selecting the bit map into a presentation space may fail. Only the active thread may use the bit-map handle returned by either the [WinQuerySysPointer](#) function, when *fCopy* is FALSE, or by the [WinQueryPointerInfo](#) function.

Note: This rule is not enforced by the system; therefore, ensure that the program handles selection failures correctly.

WinQuerySysPointer - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

PMERR_PARAMETER_OUT_OF_RANGE (0x1003)
The value of a parameter was not within the defined valid range for that parameter.

WinQuerySysPointer - Example Code

This example calls [WinQuerySysPointer](#) to get a handle to the system pointer, and then loads an application-defined pointer. After it has finished using the application-defined pointer, it restores the system pointer.

```
#define INCL_WINPOINTERS
#include <OS2.H>
#define IDP_CROSSHAIR 900

HWND hptrDefault, hptrCrossHair;
```

```

/* get the system pointer */
hptrDefault = WinQuerySysPointer(HWND_DESKTOP, SPTR_ARROW, FALSE);

/* load an application-defined pointer */
hptrCrossHair = WinLoadPointer(HWND_DESKTOP, (ULONG)0, IDP_CROSSHAIR);

/* change the pointer to the application pointer */
WinSetPointer(HWND_DESKTOP, hptrCrossHair);

/* restore the system pointer */
WinSetPointer(HWND_DESKTOP, hptrDefault);

```

WinQuerySysPointerData

WinQuerySysPointerData - Syntax

This function is specific to OS/2 Version 2.1 or higher.

This function returns the icon data for the specified system pointer for application use.

```

#define INCL_WINPOINTERS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwndDesktop; /* Handle to the desktop window. */
ULONG     iptr;         /* The index of the desired system pointer. */
PICONINFO pIconInfo;    /* Icon data buffer. */
BOOL      rc;           /* Return value. */

rc = WinQuerySysPointerData(hwndDesktop, iptr,
                             pIconInfo);

```

WinQuerySysPointerData Parameter - hwndDesktop

hwndDesktop ([HWND](#)) - input
Handle to the desktop window.

WinQuerySysPointerData Parameter - iptr

iptr ([ULONG](#)) - input
The index of the desired system pointer.

Possible values are in the following list:

SPTR_ARROW	Arrow pointer
SPTR_TEXT	Text I-beam pointer
SPTR_WAIT	Wait icon pointer
SPTR_MOVE	Move pointer
SPTR_SIZENWSE	Downward-sloping, double-headed arrow pointer
SPTR_SIZENESW	Upward-sloping, double-headed arrow pointer
SPTR_SIZEWE	Horizontal, double-headed arrow pointer
SPTR_SIZENS	Vertical, double-headed arrow pointer
SPTR_APPICON	Standard application icon pointer
SPTR_ICONINFORMATION	Information icon pointer
SPTR_ICONQUESICON	Question mark icon pointer
SPTR_ICONERROR	Exclamation mark icon pointer
SPTR_ICONWARNING	Warning icon pointer
SPTR_ILLEGAL	Illegal operation icon pointer
SPTR_FILE	Single file icon pointer
SPTR_MULTIFILE	Multiple files icon pointer
SPTR_FOLDER	Folder icon pointer
SPTR_PROGRAM	Application program icon pointer

WinQuerySysPointerData Parameter - plconInfo

plconInfo ([PICONINFO](#)) - in/out
Icon data buffer.

The pointer to the buffer the icon data is to be written into. The buffer should be large enough to accommodate the icon data.

WinQuerySysPointerData Return Value - rc

rc (**BOOL**) - returns
Return value.

TRUE	Successful.
FALSE	An error occurred.

WinQuerySysPointerData - Parameters

hwndDesktop (**HWND**) - input
Handle to the desktop window.

iptr (**ULONG**) - input
The index of the desired system pointer.

Possible values are in the following list:

SPTR_ARROW	Arrow pointer
SPTR_TEXT	Text I-beam pointer
SPTR_WAIT	Wait icon pointer
SPTR_MOVE	Move pointer
SPTR_SIZENWSE	Downward-sloping, double-headed arrow pointer
SPTR_SIZENESW	Upward-sloping, double-headed arrow pointer
SPTR_SIZEWE	Horizontal, double-headed arrow pointer
SPTR_SIZENS	Vertical, double-headed arrow pointer
SPTR_APPICON	Standard application icon pointer
SPTR_ICONINFORMATION	Information icon pointer
SPTR_ICONQUESICON	Question mark icon pointer
SPTR_ICONERROR	Exclamation mark icon pointer
SPTR_ICONWARNING	Warning icon pointer
SPTR_ILLEGAL	Illegal operation icon pointer
SPTR_FILE	Single file icon pointer
SPTR_MULTIFILE	Multiple files icon pointer
SPTR_FOLDER	Folder icon pointer
SPTR_PROGRAM	Application program icon pointer

plconInfo (**PICONINFO**) - in/out
Icon data buffer.

The pointer to the buffer the icon data is to be written into. The buffer should be large enough to accommodate the icon data.

rc ([BOOL](#)) - returns
Return value.

TRUE

Successful.

FALSE

An error occurred.

WinQuerySysPointerData - Remarks

The icon data is always returned in `ICON_DATA` format. The buffer supplied in `IconInfo` must be large enough to accommodate the icon data. If the buffer size provided is 0 or not large enough, the actual buffer size needed is returned in the [ICONINFO](#) structure.

WinQuerySystemAtomTable

WinQuerySystemAtomTable - Syntax

This function returns the handle of the system atom table.

```
#define INCL_WINATOM /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HATOMTBL    hatomtblAtomTbl; /* System atom-table handle. */

hatomtblAtomTbl = WinQuerySystemAtomTable();
```

WinQuerySystemAtomTable Return Value - hatomtblAtomTbl

hatomtblAtomTbl ([HATOMTBL](#)) - returns
System atom-table handle.

WinQuerySystemAtomTable - Parameters

hatomtblAtomTbl ([HATOMTBL](#)) - returns
System atom-table handle.

WinQuerySystemAtomTable - Remarks

The system atom table can be accessed by any process in the system. It is created at boot time and cannot be destroyed.

WinQuerySysValue

WinQuerySysValue - Syntax

This function returns a system value.

```
#define INCL_WINSYS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwndDesktop; /* Desktop-window handle. */
LONG      iSysValue;    /* System-value identity. */
LONG      lValue;       /* System value. */

lValue = WinQuerySysValue(hwndDesktop, iSysValue);
```

WinQuerySysValue Parameter - hwndDesktop

hwndDesktop ([HWND](#)) - input
Desktop-window handle.

HWND_DESKTOP
Return the system values for the desktop-window handle.

Other
Return the system values for the specified desktop-window handle.

WinQuerySysValue Parameter - iSysValue

iSysValue ([LONG](#)) - input
System-value identity.

This must be one of the following SV_* constants.

Note: Not all system values can be set with [WinSetSysValue](#); those that can be set are marked with an asterisk (*).

SV_ALARM
(*) TRUE if the alarm sound generated by [WinAlarm](#) is enabled; FALSE if the alarm sound is disabled.

SV_ALTMNEMONIC
(*) TRUE if the mnemonic is made up of KATAKANA characters; FALSE if the mnemonic is made up of ROMAN characters.

SV_ANIMATION
(*) TRUE when animation is set on. FALSE when animation is set off.

SV_BEGINDRAG
(*) Mouse begin drag (low word=mouse message id (WM_*), high word=keyboard control code (KC_*)).

SV_BEGINDRAGKB
(*) Keyboard begin drag (low word=virtual key code (VK_*), high word=keyboard control code (KC_*)).

SV_BEGINSELECT
(*) Mouse begin swipe select (low word=mouse message id (WM_*), high word=keyboard control code (KC_*)).

SV_BEGINSELECTKB
(*) Keyboard begin swipe select (low word=virtual key code (VK_*), high word=keyboard control code (KC_*)).

SV_CICONTEXTLINES
(*) Maximum number of lines that the icon text may occupy for a minimized window.

SV_CONTEXTHELP
(*) Mouse control for pop-up menu (low word=mouse message id (WM_*), high word=keyboard control code (KC_*)).

SV_CONTEXTHELPKB
(*) Keyboard control for pop-up menu (low word=virtual key code (VK_*), high word=keyboard control code (KC_*)).

SV_CONTEXTMENU
(*) Mouse request pop-up menu (low word=mouse message id (WM_*), high word=keyboard control code (KC_*)).

SV_CONTEXTMENUKB
(*) Keyboard request pop-up menu (low word=virtual key code (VK_*), high word=keyboard control code (KC_*)).

SV_CMOUSEBUTTONS
The number of buttons on the pointing device (zero if no pointing device is installed).

SV_CTIMERS
Count of available timers.

SV_CURSORLEVEL
The cursor hide level.

SV_CURSORRATE
(*) Cursor blink rate, in milliseconds.

SV_CXBORDER
Width of the nominal-width border.

SV_CXBYTEALIGN
Horizontal count of pels for alignment.

SV_CXDBLCLK
(*) Width of the pointing device double-click sensitive area. The default is the system-font character width.

SV_CXDLGFRAME
Width of the dialog-frame border.

SV_CXFULLSCREEN
Width of the client area when the window is full screen.

SV_CXHSCROLLARROW
Width of the horizontal scroll-bar arrow bit maps.

SV_CXHSLIDER
Width of the horizontal scroll-bar thumb.

SV_CXICON
Icon width.

SV_CXICONTEXTWIDTH
(*) Maximum number of characters per line allowed in the icon text for a minimized window.

SV_CXMINMAXBUTTON
Width of the minimize/maximize buttons.

SV_CXMOTIONSTART
(*) The number of pels that a pointing device must be moved in the horizontal direction, while the button is depressed, before a WM_BUTTONxMOTIONSTR message is sent.

SV_CXPOINTER
Pointer width.

SV_CXSCREEN
Width of the screen.

SV_CXSIZEBORDER
(*) Width of the sizing border.

SV_CXVSCROLL
Width of the vertical scroll-bar.

SV_CYBORDER
Height of the nominal-width border.

SV_CYBYTEALIGN
Vertical count of pels for alignment.

SV_CYDBLCLK
(*) Height of the pointing device double-click sensitive area. The default is half the height of the system font character height.

SV_CYDLGFRAME
Height of the dialog-frame border.

SV_CYFULLSCREEN
Height of the client area when the window is full screen (excluding menu height).

SV_CYHSCROLL
Height of the horizontal scroll-bar.

SV_CYICON
Icon height.

SV_CYMENU
Height of the single-line menu height.

SV_CYMINMAXBUTTON
Height of the minimize/maximize buttons.

SV_CYMOTIONSTART
(*) The number of pels that a pointing device must be moved in the vertical direction, while the button is depressed, before a WM_BUTTONxMOTIONSTR message is sent.

SV_CYPOINTER
Pointer height.

SV_CYSCREEN
Height of the screen.

SV_CYSIZEBORDER
(*) Height of the sizing border.

SV_CYTITLEBAR
Height of the caption.

SV_CYVSCROLLARROW
Height of the vertical scroll-bar arrow bit maps.

SV_CYVSLIDER
Height of the vertical scroll-bar thumb.

SV_DBLCLKTIME
(*) Pointing device double-click time, in milliseconds.

SV_DEBUG
FALSE indicates this is not a debug system.

SV_ENDDRAG
(*) Mouse end drag (low word=mouse message id (WM_*), high word=keyboard control code (KC_*)).

SV_ENDDRAGKB
(*) Keyboard end drag (low word=virtual key code (VK_*), high word=keyboard control code (KC_*)).

SV_ENDSELECT
(*) Mouse select or end swipe select (low word=mouse message id (WM_*), high word=keyboard control code (KC_*)).

SV_ENDSELECTKB
(*) Keyboard select or end swipe select (low word=virtual key code (VK_*), high word=keyboard control code (KC_*)).

SV_ERRORDURATION
(*) Duration for error alarms generated by [WinAlarm](#).

SV_ERRORFREQ
(*) Frequency for error alarms generated by [WinAlarm](#).

SV_EXTRAKEYBEEP
(*) When TRUE, the press of a key that does not exist on the Enhanced keyboard causes the system to generate a beep.

SV_FIRSTSCROLLRATE
(*) The delay (in milliseconds) before autoscrolling starts, when using a scroll bar.

SV_INSERTMODE
(*) TRUE if the system is in insert mode (for edit and multi-line edit controls); FALSE if in overwrite mode.

This system value is toggled by the system when the insert key is toggled, regardless of which window has the focus at the time.

SV_KBDALTERED
(*) Hardware ID of the newly attached keyboard.

Note: The OS/2 National Language Support is only loaded once per system IPL. The OS/2 NLS translation is based partially on the type of keyboard device attached to the system. There are two main keyboard device types:

PC AT styled and Enhanced styled. Hot Plugging between these two types of devices may result in typing anomalies due to a mismatch in the NLS device tables loaded and that of the attached device. It is strongly recommended that keyboard hot plugging be limited to the device type that the system was IPL'd with. In addition, OS/2 support will default to the 101/102 key Enhanced keyboard if no keyboard or a NetServer Mode password was in use during system IPL. (See Category 4, IOCTls 77h and 7Ah for more information on keyboard devices and types.)

SV_LOCKSTARTINPUT

(*) TRUE when the type ahead function is enabled; FALSE when the type ahead function is disabled.

SV_MENUROLLODOWNDELAY

(*) The delay in milliseconds before displaying a pull down referred to from a submenu item, when the button is already down as the pointer moves onto the submenu item.

SV_MENUROLLUPDELAY

(*) The delay in milliseconds before hiding a pull down referred to from a submenu item, when the button is already down as the pointer moves off the submenu item.

SV_MONOICONS

(*) When TRUE preference is given to black and white icons when selecting which icon resource definition to use on the screen. Black and white icons may have more clarity than color icons on LCD and Plasma display screens.

SV_MOUSEPRESENT

When TRUE a mouse pointing device is attached to the system.

SV_NOTEDURATION

(*) Duration for note alarms generated by [WinAlarm](#).

SV_NOTEFREQ

(*) Frequency for note alarms generated by [WinAlarm](#).

SV_OPEN

(*) Mouse open (low word=mouse message id (WM_*), high word=keyboard control code (KC_*)).

SV_OPENKB

(*) Keyboard open (low word=virtual key code (VK_*), high word=keyboard control code (KC_*)).

SV_POINTERLEVEL

Pointer hide level. If the pointer level is zero, the pointer is visible. If it is greater than zero, the pointer is not visible. The [WinShowPointer](#) call is invoked to increment and decrement the SV_POINTERLEVEL, but its value cannot become negative.

SV_PRINTSCREEN

(*) TRUE when the Print Screen function is enabled; FALSE when the Print Screen function is disabled.

SV_SCROLLRATE

(*) The delay (in milliseconds) between scroll operations, when using a scroll bar.

SV_SETLIGHTS

(*) When TRUE, the appropriate light is set when the keyboard state table is set.

SV_SINGLESELECT

(*) Mouse select (low word=mouse message id (WM_*), high word=keyboard control code (KC_*)).

SV_TASKLISTMOUSEACCESS

(*) Determines whether the task list is displayed when mouse buttons 1 and 2 are pressed simultaneously, or when mouse button 2 is pressed by itself, or for no mouse gesture.

SV_TEXTEDIT

(*) Mouse begin direct name edit (low word=mouse message id (WM_*), high word=keyboard control code (KC_*)).

SV_TEXTEDITKB

(*) Keyboard begin direct name edit (low word=virtual key code (VK_*), high word=keyboard control code (KC_*)).

SV_TRACKRECTLEVEL

The hide level of the tracking rectangle (zero if visible, greater than zero if not).

SV_SWAPBUTTON

(*) TRUE if pointing device buttons are swapped. Normally, the pointing device buttons are set for right-handed use. Setting this value changes them for left-handed use.

If TRUE, WM_LBUTTONDOWN* messages are returned when the user presses the right button, and WM_RBUTTONDOWN* messages are returned when the left button is pressed. Modifying this value affects the entire system. Applications

should not normally read or set this value; users update this value by means of the user interface shell to suit their requirements.

SV_WARNINGDURATION

(*) Duration for warning alarms generated by [WinAlarm](#).

SV_WARNINGFREQ

(*) Frequency for warning alarms generated by [WinAlarm](#).

WinQuerySysValue Return Value - IValue

IValue ([LONG](#)) - returns

System value.

0

Error occurred

Other

System value. Dimensions are in pels and times are in milliseconds.

WinQuerySysValue - Parameters

hwndDeskTop ([HWND](#)) - input

Desktop-window handle.

HWND_DESKTOP

Return the system values for the desktop-window handle.

Other

Return the system values for the specified desktop-window handle.

iSysValue ([LONG](#)) - input

System-value identity.

This must be one of the following SV_* constants.

Note: Not all system values can be set with [WinSetSysValue](#); those that can be set are marked with an asterisk (*).

SV_ALARM

(*) TRUE if the alarm sound generated by [WinAlarm](#) is enabled; FALSE if the alarm sound is disabled.

SV_ALTMNEMONIC

(*) TRUE if the mnemonic is made up of KATAKANA characters; FALSE if the mnemonic is made up of ROMAN characters.

SV_ANIMATION

(*) TRUE when animation is set on. FALSE when animation is set off.

SV_BEGINDRAG

(*) Mouse begin drag (low word=mouse message id (WM_*), high word=keyboard control code (KC_*)).

SV_BEGINDRAGKB

(*) Keyboard begin drag (low word=virtual key code (VK_*), high word=keyboard control code (KC_*)).

SV_BEGINSELECT

(*) Mouse begin swipe select (low word=mouse message id (WM_*), high word=keyboard control code (KC_*)).

SV_BEGINSELECTKB

(*) Keyboard begin swipe select (low word=virtual key code (VK_*), high word=keyboard control code (KC_*)).

SV_CICONTEXTLINES
(*) Maximum number of lines that the icon text may occupy for a minimized window.

SV_CONTEXTHELP
(*) Mouse control for pop-up menu (low word=mouse message id (WM_*), high word=keyboard control code (KC_*)).

SV_CONTEXTHELPKB
(*) Keyboard control for pop-up menu (low word=virtual key code (VK_*), high word=keyboard control code (KC_*)).

SV_CONTEXTMENU
(*) Mouse request pop-up menu (low word=mouse message id (WM_*), high word=keyboard control code (KC_*)).

SV_CONTEXTMENUKB
(*) Keyboard request pop-up menu (low word=virtual key code (VK_*), high word=keyboard control code (KC_*)).

SV_CMOUSEBUTTONS
The number of buttons on the pointing device (zero if no pointing device is installed).

SV_CTIMERS
Count of available timers.

SV_CURSORLEVEL
The cursor hide level.

SV_CURSORRATE
(*) Cursor blink rate, in milliseconds.

SV_CXBORDER
Width of the nominal-width border.

SV_CXBYTEALIGN
Horizontal count of pels for alignment.

SV_CXDBLCLK
(*) Width of the pointing device double-click sensitive area. The default is the system-font character width.

SV_CXDLGFRAME
Width of the dialog-frame border.

SV_CXFULLSCREEN
Width of the client area when the window is full screen.

SV_CXHSCROLLARROW
Width of the horizontal scroll-bar arrow bit maps.

SV_CXHSLIDER
Width of the horizontal scroll-bar thumb.

SV_CXICON
Icon width.

SV_CXICONTEXTWIDTH
(*) Maximum number of characters per line allowed in the icon text for a minimized window.

SV_CXMINMAXBUTTON
Width of the minimize/maximize buttons.

SV_CXMOTIONSTART
(*) The number of pels that a pointing device must be moved in the horizontal direction, while the button is depressed, before a WM_BUTTONxMOTIONSTR message is sent.

SV_CXPOINTER
Pointer width.

SV_CXSCREEN
Width of the screen.

SV_CXSIZEBORDER
(*) Width of the sizing border.

SV_CXVSCROLL

Width of the vertical scroll-bar.

SV_CYBORDER
Height of the nominal-width border.

SV_CYBYTEALIGN
Vertical count of pels for alignment.

SV_CYDBLCLK
(*) Height of the pointing device double-click sensitive area. The default is half the height of the system font character height.

SV_CYDLGFRAME
Height of the dialog-frame border.

SV_CYFULLSCREEN
Height of the client area when the window is full screen (excluding menu height).

SV_CYHSCROLL
Height of the horizontal scroll-bar.

SV_CYICON
Icon height.

SV_CYMENU
Height of the single-line menu height.

SV_CYMINMAXBUTTON
Height of the minimize/maximize buttons.

SV_CYMOTIONSTART
(*) The number of pels that a pointing device must be moved in the vertical direction, while the button is depressed, before a WM_BUTTONxMOTIONSTR message is sent.

SV_CYPOINTER
Pointer height.

SV_CYSCREEN
Height of the screen.

SV_CYSIZEBORDER
(*) Height of the sizing border.

SV_CYTITLEBAR
Height of the caption.

SV_CYVSCROLLARROW
Height of the vertical scroll-bar arrow bit maps.

SV_CYVSLIDER
Height of the vertical scroll-bar thumb.

SV_DBLCLKTIME
(*) Pointing device double-click time, in milliseconds.

SV_DEBUG
FALSE indicates this is not a debug system.

SV_ENDDRAG
(*) Mouse end drag (low word=mouse message id (WM_*), high word=keyboard control code (KC_*)).

SV_ENDDRAGKB
(*) Keyboard end drag (low word=virtual key code (VK_*), high word=keyboard control code (KC_*)).

SV_ENDSELECT
(*) Mouse select or end swipe select (low word=mouse message id (WM_*), high word=keyboard control code (KC_*)).

SV_ENDSELECTKB
(*) Keyboard select or end swipe select (low word=virtual key code (VK_*), high word=keyboard control code (KC_*)).

SV_ERRORDURATION

(*) Duration for error alarms generated by [WinAlarm](#).

SV_ERRORFREQ

(*) Frequency for error alarms generated by [WinAlarm](#).

SV_EXTRAKEYBEEP

(*) When TRUE, the press of a key that does not exist on the Enhanced keyboard causes the system to generate a beep.

SV_FIRSTSCROLLRATE

(*) The delay (in milliseconds) before autoscrolling starts, when using a scroll bar.

SV_INSERTMODE

(*) TRUE if the system is in insert mode (for edit and multi-line edit controls); FALSE if in overtype mode.

This system value is toggled by the system when the insert key is toggled, regardless of which window has the focus at the time.

SV_KBDALTERED

(*) Hardware ID of the newly attached keyboard.

Note: The OS/2 National Language Support is only loaded once per system IPL. The OS/2 NLS translation is based partially on the type of keyboard device attached to the system. There are two main keyboard device types: PC AT styled and Enhanced styled. Hot Plugging between these two types of devices may result in typing anomalies due to a mismatch in the NLS device tables loaded and that of the attached device. It is strongly recommended that keyboard hot plugging be limited to the device type that the system was IPL'd with. In addition, OS/2 support will default to the 101/102 key Enhanced keyboard if no keyboard or a NetServer Mode password was in use during system IPL. (See Category 4, IOCTls 77h and 7Ah for more information on keyboard devices and types.)

SV_LOCKSTARTINPUT

(*) TRUE when the type ahead function is enabled; FALSE when the type ahead function is disabled.

SV_MENUROLLDOWNDELAY

(*) The delay in milliseconds before displaying a pull down referred to from a submenu item, when the button is already down as the pointer moves onto the submenu item.

SV_MENUROLLUPDELAY

(*) The delay in milliseconds before hiding a pull down referred to from a submenu item, when the button is already down as the pointer moves off the submenu item.

SV_MONOICONS

(*) When TRUE preference is given to black and white icons when selecting which icon resource definition to use on the screen. Black and white icons may have more clarity than color icons on LCD and Plasma display screens.

SV_MOUSEPRESENT

When TRUE a mouse pointing device is attached to the system.

SV_NOTEDURATION

(*) Duration for note alarms generated by [WinAlarm](#).

SV_NOTEFREQ

(*) Frequency for note alarms generated by [WinAlarm](#).

SV_OPEN

(*) Mouse open (low word=mouse message id (WM_*), high word=keyboard control code (KC_*)).

SV_OPENKB

(*) Keyboard open (low word=virtual key code (VK_*), high word=keyboard control code (KC_*)).

SV_POINTERLEVEL

Pointer hide level. If the pointer level is zero, the pointer is visible. If it is greater than zero, the pointer is not visible. The [WinShowPointer](#) call is invoked to increment and decrement the SV_POINTERLEVEL, but its value cannot become negative.

SV_PRINTSCREEN

(*) TRUE when the Print Screen function is enabled; FALSE when the Print Screen function is disabled.

SV_SCROLLRATE

(*) The delay (in milliseconds) between scroll operations, when using a scroll bar.

SV_SETLIGHTS

(*) When TRUE, the appropriate light is set when the keyboard state table is set.

SV_SINGLESELECT
 (*) Mouse select (low word=mouse message id (WM_*), high word=keyboard control code (KC_*)).

SV_TASKLISTMOUSEACCESS
 (*) Determines whether the task list is displayed when mouse buttons 1 and 2 are pressed simultaneously, or when mouse button 2 is pressed by itself, or for no mouse gesture.

SV_TEXTEDIT
 (*) Mouse begin direct name edit (low word=mouse message id (WM_*), high word=keyboard control code (KC_*)).

SV_TEXTEDITKB
 (*) Keyboard begin direct name edit (low word=virtual key code (VK_*), high word=keyboard control code (KC_*)).

SV_TRACKRECTLEVEL
 The hide level of the tracking rectangle (zero if visible, greater than zero if not).

SV_SWAPBUTTON
 (*) TRUE if pointing device buttons are swapped. Normally, the pointing device buttons are set for right-handed use. Setting this value changes them for left-handed use.

If TRUE, WM_LBUTTONDOWN* messages are returned when the user presses the right button, and WM_RBUTTONDOWN* messages are returned when the left button is pressed. Modifying this value affects the entire system. Applications should not normally read or set this value; users update this value by means of the user interface shell to suit their requirements.

SV_WARNINGDURATION
 (*) Duration for warning alarms generated by [WinAlarm](#).

SV_WARNINGFREQ
 (*) Frequency for warning alarms generated by [WinAlarm](#).

IValue ([LONG](#)) - returns
 System value.

0
 Error occurred

Other
 System value. Dimensions are in pels and times are in milliseconds.

WinQuerySysValue - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
 An invalid window handle was specified.

PMERR_PARAMETER_OUT_OF_RANGE (0x1003)
 The value of a parameter was not within the defined valid range for that parameter.

WinQuerySysValue - Related Functions

Related Functions

- [WinQuerySysValue](#)
- [WinSetSysValue](#)

WinQuerySysValue - Example Code

This example uses the WinQuerySysValue function to query the sizing border dimensions.

```
#define INCL_WINSYS
#include <OS2.H>

LONG vlXBorder, vlYBorder;

vlXBorder = WinQuerySysValue(HWND_DESKTOP,
                             SV_CXSIZEBORDER);
vlYBorder = WinQuerySysValue(HWND_DESKTOP,
                             SV_CYSIZEBORDER);
```

WinQueryTaskSizePos

WinQueryTaskSizePos - Syntax

This function obtains the recommended size, position and status for the first window of a newly started application (typically the main window).

```
#define INCL_WINSWITCHLIST /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab; /* Anchor-block handle. */
ULONG    ulID; /* Session. */
PSWP     pswp; /* Window position and size data. */
ULONG    rc; /* Return code. */

rc = WinQueryTaskSizePos(hab, ulID, pswp);
```

WinQueryTaskSizePos Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinQueryTaskSizePos Parameter - ulID

ulID ([ULONG](#)) - input
Session.

If zero is specified, the session number of the caller is used.

WinQueryTaskSizePos Parameter - pswp

pswp ([PSWP](#)) - output
Window position and size data.

Contains the recommended size and position for the first (main) window of the application. The window flags are set to indicate whether this window should be activated, minimized, or maximized.

WinQueryTaskSizePos Return Value - rc

rc ([ULONG](#)) - returns
Return code.

0	Successful completion
Other	Error occurred.

WinQueryTaskSizePos - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

ulID ([ULONG](#)) - input
Session.

If zero is specified, the session number of the caller is used.

pswp ([PSWP](#)) - output
Window position and size data.

```
WinSetWindowPos(hwndFrame, HWND_TOP,
    winpos.x,          /* x pos */
    winpos.y,          /* y pos */
    winpos.cx,         /* x size */
    winpos.cy,         /* y size */
    SWP_ACTIVATE | SWP_MOVE | SWP_SIZE | SWP_SHOW); /* flags*/
```

WinQueryTaskTitle

WinQueryTaskTitle - Syntax

This function obtains the title under which a specified application is started, or is added to the Window List. (See also [WinQuerySessionTitle](#), which you should use for preference.)

```
#define INCL_WINSWITCHLIST /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

ULONG    ulSession;    /* Session identity of application whose title is requested. */
PSZ      pszTitle;     /* Window List title. */
ULONG    ulTitlelen;   /* Maximum length of data returnable, in bytes. */
ULONG    rc;           /* Return code. */

rc = WinQueryTaskTitle(ulSession, pszTitle,
    ulTitlelen);
```

WinQueryTaskTitle Parameter - ulSession

ulSession ([ULONG](#)) - input

Session identity of application whose title is requested.

0

Use the session identity of the caller

Other

Use the specified session identity.

WinQueryTaskTitle Parameter - pszTitle

pszTitle ([PSZ](#)) - output
Window List title.

This is the title of the application with a process identity, if the application is present in the Window List.

WinQueryTaskTitle Parameter - ulTitlelen

ulTitlelen ([ULONG](#)) - input
Maximum length of data returnable, in bytes.

If the *pszTitle* parameter is longer than this, the title is truncated. However, the terminating null character is left at the end of the string. The maximum number of title characters copied is (*ulTitlelen*-1).

WinQueryTaskTitle Return Value - rc

rc ([ULONG](#)) - returns
Return code.

0	Successful completion
Other	Error occurred.

WinQueryTaskTitle - Parameters

ulSession ([ULONG](#)) - input
Session identity of application whose title is requested.

0	Use the session identity of the caller
Other	Use the specified session identity.

pszTitle ([PSZ](#)) - output
Window List title.

This is the title of the application with a process identity, if the application is present in the Window List.

ulTitlelen ([ULONG](#)) - input
Maximum length of data returnable, in bytes.

If the *pszTitle* parameter is longer than this, the title is truncated. However, the terminating null character is left at the end of the string. The maximum number of title characters copied is (*ulTitleLen*-1).

rc ([ULONG](#)) - returns
Return code.

0	Successful completion
Other	Error occurred.

WinQueryTaskTitle - Remarks

This function is useful when an application uses the same name in its window title (and in its entry in the Window List) as the end user invokes to start the application. This provides a visual link for the end user.

If this function is used after a Window List entry is created for the application, the title in the Window List entry is obtained.

WinQueryTaskTitle - Example Code

This example calls WinQueryTaskTitle to retrieve the application's title, and then sets the title bar of the frame window to that title. (The WinQuerySessionTitle could be used instead).

```
#define INCL_WINSWITCHLIST
#include <OS2.H>

HAB      hab;
HWND     hwndFrame, hwndClient;
CHAR     szTitle[MAXNAMEL + 1];
HSWITCH  hswitch;
SWCNTRL  swctl;

hswitch = WinQuerySwitchHandle(hwndFrame, 0);
WinQuerySwitchEntry(hswitch, &swctl);

WinQueryTaskTitle(0,
                  szTitle,
                  sizeof(szTitle));
```

```
hwndFrame = WinQueryWindow(hwndClient,
                           QW_PARENT); /* get handle of parent, */
                                       /* which is frame window. */
WinSetWindowText(hwndFrame, szTitle);
```

WinQueryUpdateRect

WinQueryUpdateRect - Syntax

This function returns the rectangle that bounds the update region of a specified window.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwnd;      /* Handle of window whose update rectangle is to be queried. */
PRECTL    prclPrc;    /* Update region that bounds the rectangle (in window coordinates). */
BOOL      rc;         /* Success indicator. */

rc = WinQueryUpdateRect(hwnd, prclPrc);
```

WinQueryUpdateRect Parameter - hwnd

hwnd (**HWND**) - input

Handle of window whose update rectangle is to be queried.

WinQueryUpdateRect Parameter - prclPrc

prcIPrc ([PRECTL](#)) - output
Update region that bounds the rectangle (in window coordinates).

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) may also be used, if supported by the language.

WinQueryUpdateRect Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred, or window has no update region; it is wholly valid, therefore <i>prcIPrc</i> is NULL.

WinQueryUpdateRect - Parameters

hwnd ([HWND](#)) - input
Handle of window whose update rectangle is to be queried.

prcIPrc ([PRECTL](#)) - output
Update region that bounds the rectangle (in window coordinates).

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) may also be used, if supported by the language.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred, or window has no update region; it is wholly valid, therefore <i>prcIPrc</i> is NULL.

WinQueryUpdateRect - Remarks

This function is useful for implementing an incremental update scheme as an alternative to the [WinBeginPaint](#) and [WinEndPaint](#) functions.

WinQueryUpdateRect - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinQueryUpdateRect - Related Functions

Related Functions

 - [WinUpdateWindow](#)
 - [WinValidateRect](#)
 - [WinValidateRegion](#)
-

WinQueryUpdateRect - Example Code

This example assumes that `WinInvalidateRect` has been called on a window owned by this window procedure. The application is sent the `WM_PAINT` message with the entire window as the update rectangle. The window procedure gets the dimensions of the window and calls `WinValidateRect` to revalidate the window.

```
#define INCL_WINWINDOWMGR
#include <OS2.H>

HWND  hwnd;
RECT  rcl;
.
.
.
CASE WM_PAINT:

    WinQueryUpdateRect(hwnd, &rcl);
    WinValidateRect(hwnd, &rcl, FALSE);
    WinFillRect(hwnd, &rcl, CLR_RED);
    return 0L;
```

WinQueryUpdateRegion

WinQueryUpdateRegion - Syntax

This call obtains an update region of a window.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwnd;           /* Handle of window whose update region is to be queried. */
HRGN    hrgn;           /* Handle of the window's update region. */
LONG    lComplexity;    /* Complexity of resulting region/error indicator. */

lComplexity = WinQueryUpdateRegion(hwnd, hrgn);
```

WinQueryUpdateRegion Parameter - hwnd

hwnd ([HWND](#)) - input
Handle of window whose update region is to be queried.

WinQueryUpdateRegion Parameter - hrgn

hrgn ([HRGN](#)) - input
Handle of the window's update region.

The window's update region, in window coordinates, is copied into *hrgn*.

WinQueryUpdateRegion Return Value - lComplexity

lComplexity ([LONG](#)) - returns
Complexity of resulting region/error indicator.

RGN_NULL	Null region
RGN_RECT	Rectangular region
RGN_COMPLEX	Complex region
RGN_ERROR	Error.

WinQueryUpdateRegion - Parameters

hwnd ([HWND](#)) - input
Handle of window whose update region is to be queried.

hrgn ([HRGN](#)) - input
Handle of the window's update region.

The window's update region, in window coordinates, is copied into *hrgn*.

lComplexity ([LONG](#)) - returns
Complexity of resulting region/error indicator.

RGN_NULL	Null region
RGN_RECT	Rectangular region
RGN_COMPLEX	Complex region
RGN_ERROR	Error.

WinQueryUpdateRegion - Remarks

This call is useful for implementing an alternate update scheme to those used by the [WinBeginPaint](#), and [WinEndPaint](#) functions, together with the [WinValidateRegion](#) function.

The application can use the returned update region as the clip region for a presentation space, so that drawing output can be clipped to the window's update region.

WinQueryUpdateRegion - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

PMERR_HRGN_BUSY (0x2034)
An internal region busy error was detected. The region was locked by one thread during an attempt to access it from another thread.

WinQueryVersion

WinQueryVersion - Syntax

This function is included for compatibility purposes only, and its use is not recommended. It is recommended that DosQuerySysInfo (see the *Control Program Programming Reference*) be used to return the version, the revision level, and the environment of PM.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HAB      hab;      /* Anchor-block handle. */
ULONG    fSysInf;   /* System information within which the application is operating. */

fSysInf = WinQueryVersion(hab);
```

WinQueryVersion Parameter - hab

hab (**HAB**) - input
Anchor-block handle.

WinQueryVersion Return Value - fSysInf

fSysInf (**ULONG**) - returns
System information within which the application is operating.

This information consists of 4 bytes packed into the ULONG variable as follows:

- The first byte, bits 0-7, contains the major version.
- The second byte, bits 8-15, contains the minor version.
- The third byte, bits 16-23, contains the revision number.
- The fourth byte, bits 24-31, is reserved.

Version	Revision	Minor	Major
OS/2 2.0	0	00	20
OS/2 2.1	0	10	20
OS/2 2.11	0	11	20
OS/2 Warp 3.0	0	30	20

WinQueryVersion - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

fSysInf ([ULONG](#)) - returns
System information within which the application is operating.

This information consists of 4 bytes packed into the ULONG variable as follows:

- The first byte, bits 0-7, contains the major version.
- The second byte, bits 8-15, contains the minor version.
- The third byte, bits 16-23, contains the revision number.
- The fourth byte, bits 24-31, is reserved.

Version	Revision	Minor	Major
OS/2 2.0	0	00	20
OS/2 2.1	0	10	20
OS/2 2.11	0	11	20
OS/2 Warp 3.0	0	30	20

WinQueryVersion - Example Code

This example gets the version of PM that is running.

```
#define INCL_WINWINDOWMGR
#include <OS2.H>
#include <stdio.h>

HAB hab;
ULONG lVer;

lVer = WinQueryVersion(hab);
printf("PM revision is %d ", lVer);
```

WinQueryVersion - Topics

WinQueryVisibleRegion

WinQueryVisibleRegion - Syntax

This function is similar to [WinQueryUpdateRegion](#). It returns a region which could be NULL, rectangular, or complex, and represents the visible region of the window.

```
#define INCL_WINMESSAGEGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND     hwnd;    /* The window handle. */
HRGN     hrgn;    /* Region handle to receive the current visible region. */
ULONG    ulretn;

ulretn = WinQueryVisibleRegion(hwnd, hrgn);
```

WinQueryVisibleRegion Parameter - hwnd

hwnd ([HWND](#)) - input
The window handle.

WinQueryVisibleRegion Parameter - hrgn

hrgn ([HRGN](#)) - input
Region handle to receive the current visible region.

WinQueryVisibleRegion Return Value - ulretn

ulretn ([ULONG](#)) - returns

RGN_ERROR	An error occurred.
RGN_NULL	

RGN_RECT	The window currently has no visible area on screen.
RGN_COMPLEX	The region contains a series of rectangular areas.
	The region contains a complex shape.

WinQueryVisibleRegion - Parameters

hwnd ([HWND](#)) - input
The window handle.

hrgn ([HRGN](#)) - input
Region handle to receive the current visible region.

ulretn ([ULONG](#)) - returns

RGN_ERROR	An error occurred.
RGN_NULL	The window currently has no visible area on screen.
RGN_RECT	The region contains a series of rectangular areas.
RGN_COMPLEX	The region contains a complex shape.

WinQueryVisibleRegion - Remarks

This function returns the current visible region for the given window, even if that window does not receive notification when the visible region is changed. Currently, the region returned will always be a set of rectangular areas.

WinQueryWindow

WinQueryWindow - Syntax

This function returns the handle of a window that has a specified relationship to a specified window.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwnd;           /* Handle of window to query. */
LONG    lCode;          /* Type of window information. */
HWND    hwndRelated;    /* Window handle. */

hwndRelated = WinQueryWindow(hwnd, lCode);
```

WinQueryWindow Parameter - hwnd

hwnd (**HWND**) - input
Handle of window to query.

WinQueryWindow Parameter - lCode

lCode (**LONG**) - input
Type of window information.

Determines what window information is returned:

QW_NEXT	Next window in z-order (window below).
QW_PREV	Previous window in z-order (window above).
QW_TOP	Topmost child window.
QW_BOTTOM	Bottommost child window.
QW_OWNER	Owner of window.
QW_PARENT	Parent of window.

QW_NEXTTOP

Returns the next window of the owner window hierarchy subject to their z-ordering.

The enumeration is evaluated in this order:

1. The hierarchy of windows owned by this window in their z-order.
2. The hierarchy of windows of the next z-ordered window having the same owner as this window.
3. The hierarchy of windows in their z-order having the same owner as the owner of this window. This step is repeated until the top of the owner tree for this window is reached.
4. The hierarchy of windows in their z-order of unowned windows.

QW_PREVTOP

Returns the previous main window, in the enumeration order defined by QW_NEXTTOP.

QW_FRAMEOWNER

Returns the owner of *hwnd* normalized so that it shares the same parent as *hwnd*.

WinQueryWindow Return Value - hwndRelated

hwndRelated (HWND) - returns

Window handle.

Handle of window related to *hwnd*.

WinQueryWindow - Parameters

hwnd (HWND) - input

Handle of window to query.

ICode (LONG) - input

Type of window information.

Determines what window information is returned:

QW_NEXT

Next window in z-order (window below).

QW_PREV

Previous window in z-order (window above).

QW_TOP

Topmost child window.

QW_BOTTOM

Bottommost child window.

QW_OWNER

Owner of window.

QW_PARENT

Parent of window.

QW_NEXTTOP

Returns the next window of the owner window hierarchy subject to their z-ordering.

The enumeration is evaluated in this order:

1. The hierarchy of windows owned by this window in their z-order.
2. The hierarchy of windows of the next z-ordered window having the same owner as this window.
3. The hierarchy of windows in their z-order having the same owner as the owner of this window. This step is repeated until the top of the owner tree for this window is reached.
4. The hierarchy of windows in their z-order of unowned windows.

QW_PREVTOP

Returns the previous main window, in the enumeration order defined by QW_NEXTTOP.

QW_FRAMEOWNER

Returns the owner of *hwnd* normalized so that it shares the same parent as *hwnd*.

hwndRelated (HWND) - returns
Window handle.

Handle of window related to *hwnd*.

WinQueryWindow - Remarks

If this function is used to enumerate windows of other threads, it cannot be ensured that all the windows are enumerated, because the z-ordering of the windows can change during the enumeration. [WinGetNextWindow](#) must be used for this purpose.

If this function is called with QW_OWNER or QW_PARENT, the return value is [WinQueryDesktopWindow](#)(hab, NULLHANDLE), and not HWND_DESKTOP, when the desktop window is reached.

If this function is called with QW_PARENT for an object window, the return value is the handle of the object window associated with the desktop window as returned by the [WinQueryObjectWindow](#) function.

WinQueryWindow - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

PMERR_PARAMETER_OUT_OF_RANGE (0x1003)
The value of a parameter was not within the defined valid range for that parameter.

WinQueryWindow - Example Code

This example shows how to get the frame window handle from the client window handle.

```
#define INCL_WINWINDOWMGR
#define INCL_WINACCELERATORS
#include <OS2.H>

HACCEL haccel;
HWND hwndFrame, hwndClient; /* window handles. */
HAB hab; /* anchor block. */

hwndFrame = WinQueryWindow(hwndClient,
                           QW_PARENT); /* get handle of parent, */
                                       /* which is frame window. */
```

WinQueryWindowDC

WinQueryWindowDC - Syntax

This function returns the device context for a given window.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwnd; /* Window handle. */
HDC     hdc; /* Device-context handle. */

hdc = WinQueryWindowDC(hwnd);
```

WinQueryWindowDC Parameter - hwnd

hwnd ([HWND](#)) - input
Window handle.

WinQueryWindowDC Return Value - hdc

hdc ([HDC](#)) - returns
Device-context handle.

NULLHANDLE Either [WinOpenWindowDC](#) has not been called for this window, or an error has occurred.

Other Device context handle.

WinQueryWindowDC - Parameters

hwnd ([HWND](#)) - input
Window handle.

hdc ([HDC](#)) - returns
Device-context handle.

NULLHANDLE Either [WinOpenWindowDC](#) has not been called for this window, or an error has occurred.

Other Device context handle.

WinQueryWindowDC - Remarks

A handle is returned only if a device context has been opened for the window with [WinOpenWindowDC](#).

WinQueryWindowDC - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinQueryWindowModel

WinQueryWindowModel - Syntax

This function queries the memory model associated with a window.

```
#define INCL_WINTHUNKAPI /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND     hwnd;      /* Window handle. */
ULONG     ulModel;   /* Memory model associated with the window. */

ulModel = WinQueryWindowModel(hwnd);
```

WinQueryWindowModel Parameter - hwnd

hwnd (**HWND**) - input
Window handle.

WinQueryWindowModel Return Value - ulModel

ulModel (**ULONG**) - returns
Memory model associated with the window.

PM_MODEL_1X	The 16-bit memory model of the 80386 processor.
PM_MODEL_2X	The 32-bit memory model of the 80386 processor.

WinQueryWindowModel - Parameters

hwnd (**HWND**) - input
Window handle.

ulModel (**ULONG**) - returns
Memory model associated with the window.

PM_MODEL_1X	The 16-bit memory model of the 80386 processor.
PM_MODEL_2X	The 32-bit memory model of the 80386 processor.

WinQueryWindowModel - Remarks

This function enables an application to query the memory model associated with a particular window to find out whether or not conversion of application-defined data is required. This may be necessary, for example, when sending DDE data. An existing OS/2 Version 1.1 or 1.2

application does not know about pointer conversion, so its data has to be converted for use in a 32-bit application.

The memory model is determined by how the window procedure was registered. If an application calls [WinRegisterClass](#) from 32-bit code, any windows created with that class are called 32-bit windows. If the application calls [WinSubclassWindow](#) from 16-bit code on a 32-bit window, that window becomes a 16-bit window.

WinQueryWindowPos

WinQueryWindowPos - Syntax

This function queries the window size and position of a visible window.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwnd; /* Window handle. */
PSWP    pswp; /* SWP structure. */
BOOL    rc;    /* Success indicator. */

rc = WinQueryWindowPos(hwnd, pswp);
```

WinQueryWindowPos Parameter - hwnd

hwnd (**HWND**) - input
Window handle.

WinQueryWindowPos Parameter - pswp

pswp (**PSWP**) - output
SWP structure.

The fields are set such that a call to [WinSetWindowPos](#) with those values sets the window to its current size and position, with the exception of the // bits which are set as follows:

- SWP_MOVE and SWP_SIZE are set to TRUE.
- SWP_ACTIVATE and SWP_DEACTIVATE, are set to the current state of the window.
- If the window is minimized, SWP_MINIMIZE, is set and SWP_MAXIMIZE, is zero.
- If the window is maximized, SWP_MAXIMIZE, is set and SWP_MINIMIZE, is zero.
- If the window is neither minimized nor maximized, both SWP_MINIMIZE, and SWP_MAXIMIZE, are zero.
- All other bits are set to zero.

WinQueryWindowPos Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinQueryWindowPos - Parameters

hwnd ([HWND](#)) - input
Window handle.

pswp ([PSWP](#)) - output
SWP structure.

The fields are set such that a call to [WinSetWindowPos](#) with those values sets the window to its current size and position, with the exception of the // bits which are set as follows:

- SWP_MOVE and SWP_SIZE are set to TRUE.
- SWP_ACTIVATE and SWP_DEACTIVATE, are set to the current state of the window.
- If the window is minimized, SWP_MINIMIZE, is set and SWP_MAXIMIZE, is zero.
- If the window is maximized, SWP_MAXIMIZE, is set and SWP_MINIMIZE, is zero.
- If the window is neither minimized nor maximized, both SWP_MINIMIZE, and SWP_MAXIMIZE, are zero.
- All other bits are set to zero.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinQueryWindowPos - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

PMERR_INVALID_FLAG (0x1019)
An invalid bit was set for a parameter. Use constants defined by PM for options, and do not set any reserved bits.

WinQueryWindowPos - Example Code

This example shows how to center a dialog box within the Screen using WinQueryWindowPos.

```
#define INCL_WINWINDOWMGR
```

```

#define INCL_WINSYS
#include <OS2.H>
HWND hwnd;          /* window handle. */
SHORT ix, iy;
SHORT iwidth, idepth;
SWP swp;

/* Query width and height of Screen device */
iwidth = WinQuerySysValue( HWND_DESKTOP, SV_CXSCREEN );
idepth = WinQuerySysValue( HWND_DESKTOP, SV_CYSCREEN );

/* Query width and height of dialog box */
WinQueryWindowPos( hwnd, (PSWP)&swp );

/* Center dialog box within the Screen */
ix = (SHORT)(( iwidth - swp.cx ) / 2);
iy = (SHORT)(( idepth - swp.cy ) / 2);
WinSetWindowPos( hwnd, HWND_TOP, ix, iy, 0, 0, SWP_MOVE );

```

WinQueryWindowProcess

WinQueryWindowProcess - Syntax

This function obtains the process identity and thread identity of the thread that created a window.

```

#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwnd; /* Window handle. */
PPID    ppid; /* Process identity of the thread that created the window. */
PTID    ptid; /* Thread identity of the thread that created the window. */
BOOL    rc;    /* Success indicator. */

rc = WinQueryWindowProcess(hwnd, ppid, ptid);

```

WinQueryWindowProcess Parameter - hwnd

hwnd (**HWND**) - input
Window handle.

WinQueryWindowProcess Parameter - ppid

ppid (**PPID**) - output
Process identity of the thread that created the window.

WinQueryWindowProcess Parameter - ptid

ptid (**PTID**) - output
Thread identity of the thread that created the window.

WinQueryWindowProcess Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinQueryWindowProcess - Parameters

hwnd (**HWND**) - input
Window handle.

ppid (**PPID**) - output
Process identity of the thread that created the window.

ptid (**PTID**) - output
Thread identity of the thread that created the window.

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinQueryWindowProcess - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinQueryWindowPtr

WinQueryWindowPtr - Syntax

This function retrieves a pointer value from the memory of the reserved window word.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwnd;    /* Window handle which has the pointer to retrieve. */
LONG    index;    /* Zero-based index of the pointer value to retrieve. */
PVOID    pRet;    /* Pointer value. */

pRet = WinQueryWindowPtr(hwnd, index);
```

WinQueryWindowPtr Parameter - hwnd

hwnd ([HWND](#)) - input
Window handle which has the pointer to retrieve.

WinQueryWindowPtr Parameter - index

index ([LONG](#)) - input
Zero-based index of the pointer value to retrieve.

The units of *index* are bytes. Valid values are zero through (*cbWindowData* -4), where *cbWindowData* is the parameter in [WinRegisterClass](#) that specifies the number of bytes available for application-defined storage.

The value QWP_PFNWP can be used for the address of the window's window procedure.

WinQueryWindowPtr Return Value - pRet

pRet ([PVOID](#)) - returns
Pointer value.

NULL	Error occurred.
Other	Pointer value.

WinQueryWindowPtr - Parameters

hwnd ([HWND](#)) - input
Window handle which has the pointer to retrieve.

index ([LONG](#)) - input
Zero-based index of the pointer value to retrieve.

The units of *index* are bytes. Valid values are zero through (*cbWindowData* -4), where *cbWindowData* is the parameter in [WinRegisterClass](#) that specifies the number of bytes available for application-defined storage.

The value QWP_PFNWP can be used for the address of the window's window procedure.

pRet ([PVOID](#)) - returns
Pointer value.

NULL	Error occurred.
Other	Pointer value.

WinQueryWindowPtr - Remarks

The *index* parameter is valid only if all of the bytes referenced are within the reserved memory.

WinQueryWindowPtr - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

PMERR_PARAMETER_OUT_OF_RANGE (0x1003)
The value of a parameter was not within the defined valid range for that parameter.

WinQueryWindowPtr - Example Code

This function retrieves a pointer value from the memory of the reserved window word.

```
MyWindowProc(HWND hwnd, ULONG msg, MPARAM mp1, MPARAM mp2)
{
    MYINSTANCEDATA *InstanceData; /* application defined structure */

    switch (msg) {
    case WM_CREATE:
        DosAllocMem(&InstanceData, sizeof(MYINSTANCEDATA), fALLOC);
        /* WindowProcedure initializes instance data for this window */
        .
        .
        /* set pointer to instance in window words */
        WinSetWindowPtr(hwnd, 0, InstanceData);
        break;

    case WM_USER + 1: /* application defined message */
        /* Window procedure retrieves instance data to      */
        /* process this message                               */

        InstanceData = WinQueryWindowPtr(hwnd, 0);
        .
        .

        break;
        .
        .
    }
```

WinQueryWindowRect

WinQueryWindowRect - Syntax

This function returns a window rectangle.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HWND     hwnd;          /* Window handle whose rectangle is retrieved. */
PRECTL   prclDest;      /* Window rectangle. */
BOOL     rc;            /* Rectangle-returned indicator. */

rc = WinQueryWindowRect(hwnd, prclDest);
```

WinQueryWindowRect Parameter - hwnd

hwnd (**HWND**) - input
Window handle whose rectangle is retrieved.

WinQueryWindowRect Parameter - prclDest

prclDest (**PRECTL**) - output
Window rectangle.

Window rectangle of *hwnd*, in window coordinates.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type **WRECT** may also be used, if supported by the language.

WinQueryWindowRect Return Value - rc

rc (**BOOL**) - returns
Rectangle-returned indicator.

TRUE	Rectangle successfully returned
FALSE	Rectangle not successfully returned.

WinQueryWindowRect - Parameters

hwnd ([HWND](#)) - input
Window handle whose rectangle is retrieved.

prclDest ([PRECTL](#)) - output
Window rectangle.

Window rectangle of *hwnd*, in window coordinates.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) may also be used, if supported by the language.

rc ([BOOL](#)) - returns
Rectangle-returned indicator.

TRUE	Rectangle successfully returned
FALSE	Rectangle not successfully returned.

WinQueryWindowRect - Remarks

The rectangle is in window coordinates relative to itself, so that the bottom left corner is at the position (0,0).

If the size of a frame window has been changed to zero by [WinSetWindowPos](#) or [WinSetMultWindowPos](#), the original size is returned because the window is hidden, not sized, in this instance.

WinQueryWindowRect - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinQueryWindowText

WinQueryWindowText - Syntax

This function copies window text into a buffer.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND hwnd; /* Window handle. */
LONG lLength; /* Length of pun. */
PUN pun; /* Window text. */
LONG lRetLen; /* Length of returned text not including the null terminator. */

lRetLen = WinQueryWindowText(hwnd, lLength,
                             pun);
```

WinQueryWindowText Parameter - hwnd

hwnd (**HWND**) - input
Window handle.

If *hwnd* is a frame-window handle, the title-bar window text is copied.

WinQueryWindowText Parameter - ILength

ILength (**LONG**) - input
Length of *pun*.

It must be greater than 0.

WinQueryWindowText Parameter - pun

pun (**PUN**) - output
Window text.

WinQueryWindowText Return Value - IRetLen

IRetLen (**LONG**) - returns
Length of returned text not including the null terminator.

WinQueryWindowText - Parameters

hwnd (**HWND**) - input
Window handle.

If *hwnd* is a frame-window handle, the title-bar window text is copied.

ILength (**LONG**) - input
Length of *pun*.

It must be greater than 0.

pun (**PUN**) - output

Window text.

lRetLen ([LONG](#)) - returns

Length of returned text not including the null terminator.

WinQueryWindowText - Remarks

If the window text is longer than (*lLength*-1) only the first (*lLength*-1) characters of window text are copied.

If the window is the frame window, the title bar window text is copied.

This function sends a [WM_QUERYWINDOWPARAMS](#) message to *hwnd*.

If this function references the window of another process, *pwn* must be in memory that is shared by both processes, otherwise a memory fault can occur.

Note: Extreme caution must be used if this function is used to access an object window (that is, a window that is descended from `HWND_OBJECT`). This is because it is very possible that the thread that owns the object window might not be processing it's message queue, and if this is the case, a system halt could occur.

WinQueryWindowText - Errors

Possible returns from [WinGetLastError](#)

`PMERR_INVALID_HWND (0x1001)`

An invalid window handle was specified.

WinQueryWindowThunkProc

WinQueryWindowThunkProc - Syntax

This function queries the pointer-conversion procedure associated with a window.

```
#define INCL_WINTHUNKAPI /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND     hwnd; /* Window handle. */
PFN      thunkpr; /* Pointer-conversion procedure identifier. */

thunkpr = WinQueryWindowThunkProc(hwnd);
```

WinQueryWindowThunkProc Parameter - hwnd

hwnd (**HWND**) - input
Window handle.

WinQueryWindowThunkProc Return Value - thunkpr

thunkpr (**PFN**) - returns
Pointer-conversion procedure identifier.

NULL	No pointer-conversion procedure is associated with this window.
Other	Identifier of the pointer-conversion procedure associated with this window.

WinQueryWindowThunkProc - Parameters

hwnd ([HWND](#)) - input
Window handle.

thunkpr ([PFN](#)) - returns
Pointer-conversion procedure identifier.

NULL	No pointer-conversion procedure is associated with this window.
Other	Identifier of the pointer-conversion procedure associated with this window.

WinQueryWindowULong

WinQueryWindowULong - Syntax

This function obtains the unsigned long integer value, at a specified offset, from the memory of a reserved window word, of a given window.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwnd;        /* Handle of window to be queried. */
LONG     index;       /* Zero-based index into the window words of the value to be queried. */
ULONG    ulValue;     /* Value contained in the window word. */

ulValue = WinQueryWindowULong(hwnd, index);
```

WinQueryWindowULong Parameter - hwnd

hwnd ([HWND](#)) - input
Handle of window to be queried.

WinQueryWindowULong Parameter - index

index ([LONG](#)) - input
Zero-based index into the window words of the value to be queried.

The units of **index** are bytes. Valid values are zero through (*cbWindowData* -4), where *cbWindowData* is the parameter in [WinRegisterClass](#) that specifies the number of bytes available for application-defined storage. Any of the QWL_* values are valid.

Note: QWS_* values cannot be used.

QWL_DEFBUTTON
The default push button for a dialog.

The default push button is the one that sends its [WM_COMMAND](#) message when the enter key is pressed.

QWL_HMQ
Handle of message queue of window. Note that the leading 16 bits of this value are zero.

QWL_HWNDFOCUSSAVE
Window handle of the child windows of this window that last possessed the focus when this frame window was last deactivated.

QWL_PENDATA
Reserved for use by operating system extensions. It allows an operating system extension to store data on a per window basis.

QWL_STYLE
Window style.

QWL_USER
A ULONG value for applications to use is present at offset QWL_USER in windows of the following preregistered window classes:

WC_BUTTON

WC_COMBOBOX
 WC_CONTAINER
 WC_ENTRYFIELD
 WC_FRAME (includes dialog windows)
 WC_LISTBOX
 WC_MENU
 WC_MLE
 WC_NOTEBOOK
 WC_SCROLLBAR
 WC_SLIDER
 WC_SPINBUTTON
 WC_STATIC
 WC_TITTLBAR
 WC_VALUESET

This value can be used to place application-specific data in controls.

Other

Zero-based index.

WinQueryWindowULong Return Value - ulValue

ulValue ([ULONG](#)) - returns

Value contained in the window word.

WinQueryWindowULong - Parameters

hwnd ([HWND](#)) - input

Handle of window to be queried.

index ([LONG](#)) - input

Zero-based index into the window words of the value to be queried.

The units of **index** are bytes. Valid values are zero through (*cbWindowData* -4), where *cbWindowData* is the parameter in [WinRegisterClass](#) that specifies the number of bytes available for application-defined storage. Any of the QWL_* values are valid.

Note: QWS_* values cannot be used.

QWL_DEFBUTTON

The default push button for a dialog.

The default push button is the one that sends its [WM_COMMAND](#) message when the enter key is pressed.

QWL_HMQ

Handle of message queue of window. Note that the leading 16 bits of this value are zero.

QWL_HWNDFOCUSSAVE

Window handle of the child windows of this window that last possessed the focus when this frame window was last deactivated.

QWL_PENDATA

Reserved for use by operating system extensions. It allows an operating system extension to store data on a per window basis.

QWL_STYLE

Window style.

QWL_USER

A ULONG value for applications to use is present at offset QWL_USER in windows of the following preregistered window classes:

WC_BUTTON
WC_COMBOBOX
WC_CONTAINER
WC_ENTRYFIELD
WC_FRAME (includes dialog windows)
WC_LISTBOX
WC_MENU
WC_MLE
WC_NOTEBOOK
WC_SCROLLBAR
WC_SLIDER
WC_SPINBUTTON
WC_STATIC
WC_TITTLBAR
WC_VALUESET

This value can be used to place application-specific data in controls.

Other

Zero-based index.

ulValue ([ULONG](#)) - returns
Value contained in the window word.

WinQueryWindowULong - Remarks

The window handle that is passed to this function can be the handle of a window with the same, or different, message queue as the caller, thereby allowing the caller to obtain data from windows belonging to other threads.

The specified *index* is valid only if all of the bytes referenced are within the reserved memory.

WinQueryWindowULong - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

PMERR_PARAMETER_OUT_OF_RANGE (0x1003)
The value of a parameter was not within the defined valid range for that parameter.

WinQueryWindowUShort

WinQueryWindowUShort - Syntax

This function obtains the unsigned short integer value at a specified offset from the reserved window word's memory of a given window.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwnd;      /* Handle of window to be queried. */
LONG    index;     /* Zero-based index into the window words of the value to be queried. */
USHORT  usValue;    /* Value contained in the indicated window word. */

usValue = WinQueryWindowUShort(hwnd, index);
```

WinQueryWindowUShort Parameter - hwnd

hwnd (**HWND**) - input
Handle of window to be queried.

WinQueryWindowUShort Parameter - index

index (**LONG**) - input
Zero-based index into the window words of the value to be queried.

The units of *index* are bytes. Valid values are zero through (*cbWindowData* -2), where *cbWindowData* is the parameter in [WinRegisterClass](#) that specifies the number of bytes available for application-defined storage. Any of the QWS_* values are valid.

Note: QWL_* values cannot be used.

QWS_CXRESTORE
The width to which the window is restored.

See also the QWS_CYRESTORE value.

QWS_CYRESTORE
The height to which the window is restored.

These values are only valid while the window is maximized or minimized (that is, while either the WS_MINIMIZED or WS_MAXIMIZED window style indicators are set). Changing these values with the [WinSetWindowUShort](#) call alters the restore size and position.

QWS_FLAGS
These indicators apply only to frame or dialog windows, and contain combinations of the following indicators:

FF_ACTIVE	Frame window is displayed in the active state.
FF_DIALOGBOX	Frame window is being used as a dialog box.
FF_DLGDISMISSED	Dialog has been dismissed by the WinDismissDlg function.
FF_FLASHHILITE	Window is currently flashed. This indicator toggles with each flash.
FF_FLASHWINDOW	Frame window is flashing.
FF_OWNERDISABLED	Window's owner is disabled. This indicator is only set if the window and its owner are siblings.
FF_OWNERHIDDEN	Frame window is hidden as a result of its owner being hidden or minimized. This indicator is set only if the window and its owner are siblings.
FF_SELECTED	Frame window is selected.

QWS_ID
Window identity. The value of the *id* parameter of the [WinCreateWindow](#) function.

QWS_RESULT
Dialog-result parameter, as established by the [WinDismissDlg](#) function.

QWS_XMINIMIZE
The x-coordinate of the position to which the window is minimized. If this value is -1, the window has not been minimized.

See also the QWS_YMINIMIZE value.

QWS_XRESTORE

The x-coordinate of the position to which the window is restored.

See also the QWS_CYRESTORE value.

QWS_YMINIMIZE

The y-coordinate of the position to which the window is minimized.

When the window is minimized for the first time an arbitrary position is chosen. Changing these values with the [WinSetWindowUShort](#) call alters the position of the minimized window, but only when the window is not in a minimized state.

QWS_YRESTORE

The y-coordinate of the position to which the window is restored.

See also the QWS_CYRESTORE value.

Other

Zero-based index.

WinQueryWindowUShort Return Value - usValue

usValue ([USHORT](#)) - returns

Value contained in the indicated window word.

WinQueryWindowUShort - Parameters

hwnd ([HWND](#)) - input

Handle of window to be queried.

index ([LONG](#)) - input

Zero-based index into the window words of the value to be queried.

The units of *index* are bytes. Valid values are zero through (*cbWindowData* -2), where *cbWindowData* is the parameter in [WinRegisterClass](#) that specifies the number of bytes available for application-defined storage. Any of the QWS_* values are valid.

Note: QWL_* values cannot be used.

QWS_CXRESTORE

The width to which the window is restored.

See also the QWS_CYRESTORE value.

QWS_CYRESTORE

The height to which the window is restored.

These values are only valid while the window is maximized or minimized (that is, while either the WS_MINIMIZED or WS_MAXIMIZED window style indicators are set). Changing these values with the [WinSetWindowUShort](#) call alters the restore size and position.

QWS_FLAGS

These indicators apply only to frame or dialog windows, and contain combinations of the following indicators:

FF_ACTIVE

Frame window is displayed in the active state.

FF_DIALOGBOX

Frame window is being used as a dialog box.

FF_DLGDISMISSED

Dialog has been dismissed by the [WinDismissDlg](#) function.

FF_FLASHHILITE	Window is currently flashed. This indicator toggles with each flash.
FF_FLASHWINDOW	Frame window is flashing.
FF_OWNERDISABLED	Window's owner is disabled. This indicator is only set if the window and its owner are siblings.
FF_OWNERHIDDEN	Frame window is hidden as a result of its owner being hidden or minimized. This indicator is set only if the window and its owner are siblings.
FF_SELECTED	Frame window is selected.
QWS_ID	Window identity. The value of the <i>id</i> parameter of the WinCreateWindow function.
QWS_RESULT	Dialog-result parameter, as established by the WinDismissDlg function.
QWS_XMINIMIZE	The x-coordinate of the position to which the window is minimized. If this value is -1, the window has not been minimized. See also the QWS_YMINIMIZE value.
QWS_XRESTORE	The x-coordinate of the position to which the window is restored. See also the QWS_CYRESTORE value.
QWS_YMINIMIZE	The y-coordinate of the position to which the window is minimized. When the window is minimized for the first time an arbitrary position is chosen. Changing these values with the WinSetWindowUShort call alters the position of the minimized window, but only when the window is not in a minimized state.
QWS_YRESTORE	The y-coordinate of the position to which the window is restored. See also the QWS_CYRESTORE value.
Other	Zero-based index.
usValue (USHORT) - returns Value contained in the indicated window word.	

WinQueryWindowUShort - Remarks

The window handle that is passed to this function can be the handle of a window with the same, or different, message queue as the caller, thereby allowing the caller to obtain data from windows belonging to other threads.

WinQueryWindowUShort - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

PMERR_PARAMETER_OUT_OF_RANGE (0x1003)

The value of a parameter was not within the defined valid range for that parameter.

WinRealizePalette

WinRealizePalette - Syntax

This function indicates that drawing is about to take place after a palette has been selected.

```
#define INCL_WIN /* Or use INCL_PM, */  
#include <os2.h>  
  
HWND      hwnd;      /* Window handle where drawing is taking place. */  
HPS       hps;       /* Presentation-space handle. */  
PULONG    pcclr;     /* Number of physical palette entries changed. */  
LONG      lChanged;  /* Number of colors remapped. */  
  
lChanged = WinRealizePalette(hwnd, hps, pcclr);
```

WinRealizePalette Parameter - hwnd

hwnd ([HWND](#)) - input
Window handle where drawing is taking place.

WinRealizePalette Parameter - hps

hps ([HPS](#)) - input
Presentation-space handle.

WinRealizePalette Parameter - pcclr

pcclr ([PULONG](#)) - output
Number of physical palette entries changed.

A value of zero indicates that the palette was successfully realized without changing any entries in the display hardware physical

table. A non-zero value gives the number of hardware table entries that were changed and indicates that a [WM_REALIZEPALETTE](#) message has been posted to all other applications.

WinRealizePalette Return Value - IChanged

IChecked (LONG) - returns

Number of colors remapped.

PAL_ERROR

Error occurred

Otherwise

Number of colors that are remapped. This includes both animating and non-animating indexes that have matches in the physical palette. This information can be used to determine whether the window needs repainting.

Note that this information may already be out of date if there are other palette-using applications running.

WinRealizePalette - Parameters

hwnd (HWND) - input

Window handle where drawing is taking place.

hps (HPS) - input

Presentation-space handle.

pcclr (PULONG) - output

Number of physical palette entries changed.

A value of zero indicates that the palette was successfully realized without changing any entries in the display hardware physical table. A non-zero value gives the number of hardware table entries that were changed and indicates that a [WM_REALIZEPALETTE](#) message has been posted to all other applications.

IChecked (LONG) - returns

Number of colors remapped.

PAL_ERROR

Error occurred

Otherwise

Number of colors that are remapped. This includes both animating and non-animating indexes that have matches in the physical palette. This information can be used to determine whether the window needs repainting.

Note that this information may already be out of date if there are other palette-using applications running.

WinRealizePalette - Remarks

This function is typically used after GpiSelectPalette or in response to a [WM_REALIZEPALETTE](#) message. It causes the system to ensure that the palette is appropriately realized for all drawing operations.

When the window has the input focus, the palette will be realized absolutely. Otherwise, the realization is on a best-can-do basis. If the palette is larger than the currently associated device can support, as many entries as possible are realized, starting from the lowest index.

If the presentation space is currently associated with a device context of type OD_MEMORY (see [DevOpenDC](#)), then this function performs no function other than returning without error.

This function must not be called while processing a [WM_SETFOCUS](#) message, because a window's activation state is not known until processing of this message is complete.

Note that the palette cannot be physically changed on all devices. The effect of this call is therefore device dependent.

WinRealizePalette - Errors

Possible returns from [WinGetLastError](#)

PMERR_NO_PALETTE_SELECTED (0x2110)

An attempt to realize a palette failed because no palette was previously selected into the Presentation Space.

PMERR_INVALID_HWND (0x1001)

An invalid window handle was specified.

PMERR_INV_HDC (0x207C)

An invalid device-context handle or (micro presentation space) presentation-space handle was specified.

PMERR_HDC_BUSY (0x2033)

An internal device context busy error was detected. The device context was locked by one thread during an attempt to access it from another thread.

PMERR_INV_IN_AREA (0x2085)

An attempt was made to issue a function invalid inside an area bracket. This can be detected while the actual drawing mode is **draw** or **draw-and-retain** or during segment drawing or correlation functions.

WinRegisterClass

WinRegisterClass - Syntax

This function registers a window class.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
```

```
#include <os2.h>

HAB      hab;           /* Anchor-block handle. */
PSZ      pszClassName;  /* Window-class name. */
PFNWP    pfnWndProc;    /* Window-procedure identifier. */
ULONG    flStyle;       /* Default-window style. */
ULONG    cbWindowData;  /* Reserved storage. */
BOOL     rc;            /* Window-class-registration indicator. */

rc = WinRegisterClass(hab, pszClassName, pfnWndProc,
                     flStyle, cbWindowData);
```

WinRegisterClass Parameter - hab

hab (**HAB**) - input
Anchor-block handle.

WinRegisterClass Parameter - pszClassName

pszClassName (**PSZ**) - input
Window-class name.

An application-specified class name.

WinRegisterClass Parameter - pfnWndProc

pfnWndProc (**PFNWP**) - input
Window-procedure identifier.

Can be NULL if the application does not provide its own window procedure.

WinRegisterClass Parameter - flStyle

flStyle (**ULONG**) - input
Default-window style.

This can be any of the standard class styles (CS_*) in addition to any class-specific styles that are defined. These styles can be augmented when a window of this class is created.

A public window class is created if the CS_PUBLIC style is specified, otherwise a private class is created. The CS_PUBLIC style must only be specified for the shell process.

Public classes are available for creating windows from any process. Private classes are only available to the registering process.

WinRegisterClass Parameter - cbWindowData

cbWindowData ([ULONG](#)) - input
Reserved storage.

This is the number of bytes of storage reserved per window created of this class for application use.

WinRegisterClass Return Value - rc

rc ([BOOL](#)) - returns
Window-class-registration indicator.

TRUE	Window class successfully registered
FALSE	Window class not successfully registered.

WinRegisterClass - Parameters

hAb ([HAB](#)) - input
Anchor-block handle.

pszClassName ([PSZ](#)) - input
Window-class name.

An application-specified class name.

pfnWndProc ([PFNWP](#)) - input
Window-procedure identifier.

Can be NULL if the application does not provide its own window procedure.

flStyle ([ULONG](#)) - input
Default-window style.

This can be any of the standard class styles (CS_*) in addition to any class-specific styles that are defined. These styles can be augmented when a window of this class is created.

A public window class is created if the CS_PUBLIC style is specified, otherwise a private class is created. The CS_PUBLIC style must only be specified for the shell process.

Public classes are available for creating windows from any process. Private classes are only available to the registering process.

cbWindowData ([ULONG](#)) - input
Reserved storage.

This is the number of bytes of storage reserved per window created of this class for application use.

rc ([BOOL](#)) - returns
Window-class-registration indicator.

TRUE

FALSE	Window class successfully registered
	Window class not successfully registered.

WinRegisterClass - Remarks

When an application registers a private class with the window procedure in a dynamic link library, it is the application's responsibility to resolve the window-procedure address before issuing this function.

A private class must not be registered with the same name as a public class in the same process.

However, if a private class is registered with the same name as one that already exists, the parameters replace the old class parameters, and the return value is TRUE. The window procedure of an existing window can be changed using [WinSubclassWindow](#) or [WinSetWindowPtr](#). The style of an existing window can be changed with the [WinSetWindowULong](#) or [WinSetWindowUShort](#) functions. The number of bytes of storage allocated for application use cannot be changed once the window is created.

Private classes are deleted when the process that registers them terminates.

WinRegisterClass - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_FLAG (0x1019)

An invalid bit was set for a parameter. Use constants defined by PM for options, and do not set any reserved bits.

PMERR_INVALID_INTEGER_ATOM (0x1016)

The specified atom is not a valid integer atom.

PMERR_INVALID_HATOMTBL (0x1013)

An invalid atom-table handle was specified.

PMERR_INVALID_ATOM_NAME (0x1015)

An invalid atom name string was passed.

PMERR_ATOM_NAME_NOT_FOUND (0x1017)

The specified atom name is not in the atom table.

WinRegisterObjectClass

WinRegisterObjectClass - Syntax

The WinRegisterObjectClass function registers a workplace object class.

```
#define INCL_WINWORKPLACE
#include <os2.h>

PSZ pClassName; /* A pointer to object class being registered. */
PSZ pModname; /* A pointer to DLL name. */
BOOL rc; /* Success indicator. */

rc = WinRegisterObjectClass(pClassName, pModname);
```

WinRegisterObjectClass Parameter - pClassName

pClassName (PSZ) - input
A pointer to object class being registered.

A pointer to a zero-terminated string which contains the name of the object class being registered in the workplace.

WinRegisterObjectClass Parameter - pModname

pModname (PSZ) - input
A pointer to DLL name.

A pointer to a zero-terminated string which contains the name of the DLL which holds the object definition.

WinRegisterObjectClass Return Value - rc

rc (BOOL) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinRegisterObjectClass - Parameters

pClassName (PSZ) - input
A pointer to object class being registered.

A pointer to a zero-terminated string which contains the name of the object class being registered in the workplace.

pModname (PSZ) - input
A pointer to DLL name.

A pointer to a zero-terminated string which contains the name of the DLL which holds the object definition.

rc (BOOL) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinRegisterObjectClass - Remarks

The DLL must be one created using the IBM System Object Model. Object classes will automatically be added to the system when installing a DLL which contains an object definition. Generally, it is not required for the object DLL to be present at the time WinRegisterObjectClass is called. However, if the object class overrides wpclsQueryInstanceType or wpclsQueryInstanceFilter, the DLL must be present at the time of the class registration.

WinRegisterUserDatatype

WinRegisterUserDatatype - Syntax

This function registers a data type and defines its structure.

```
#define INCL_WINMESSAGEGR /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
LONG      datatype;     /* Data type code to be defined. */
LONG      count;        /* Number of elements. */
PLONG     types;        /* Data type codes of structure components. */
BOOL      rc;           /* Success indicator. */

rc = WinRegisterUserDatatype(hab, datatype,
                             count, types);
```

WinRegisterUserDatatype Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinRegisterUserDatatype Parameter - datatype

datatype ([LONG](#)) - input
Data type code to be defined.

This must not be less than DTYP_USER, and must not have been defined previously.

WinRegisterUserDatatype Parameter - count

count ([LONG](#)) - input
Number of elements.

Must not be less than one.

WinRegisterUserDatatype Parameter - types

types ([PLONG](#)) - input
Data type codes of structure components.

Valid data types are the system-defined data types and their pointer equivalents, application-defined data types and their pointer equivalents, and control data types. Note that not all of the data types that occur in the CPI can be specified on this function.

A control data type is followed by one or more entries in the *types* array that are interpreted in a special way. Control data types allow arrays, offsets, and lengths to be defined.

Simple Data Types:

DTYP_ATOM	See ATOM .
DTYP_BIT16	See USHORT .
DTYP_BIT32	See ULONG .
DTYP_BIT8	See UCHAR .
DTYP_BOOL	See BOOL .

Pointer to an item of data type DTYP_*, where DTYP_* is one of the data types in the preceding lists. The value of a pointer data type is the value of the corresponding non-pointer data type prefixed with a minus to make it negative.

Minimum Application Data Type:

DTYP_USER

Minimum value for application-defined non-pointer data types.

Control Data Type:

DTYP_CTL_ARRAY

This starts a sequence of three array elements that define an array; the array resides in the structure being defined, and may have a fixed number of elements or a variable number of elements.

The following describes the possible elements:

n	DTYP_CTL_ARRAY
n+1	data type of array data.
n+2	minus the number of elements in the array (for an array of fixed size), or the index of the element in <i>types</i> corresponding to the structure component which contains the number of elements in the array being defined. This component must have a suitable numeric data type. The array-size element must precede element "n" in <i>types</i> . The index is zero-based.

DTYP_CTL_LENGTH

This starts a sequence of four array elements that define a structure component containing the length of part or all of the structure. The length component resides at this point in the structure.

The following describes the possible elements:

n	DYP_CTL_LENGTH
---	----------------

	n+1	data type of structure component that contains the length (must be a suitable numeric data type).														
	n+2	<p>the index of the element in <i>types</i> corresponding to the first structure component that is included in the length; a value of -1 denotes the start of the structure. This index is zero-based.</p> <p>The element specified must not be one that is the second or subsequent element in a DTYP_CTL_* sequence of elements.</p>														
	N+3	<p>the index of the element in <i>types</i> corresponding to the last structure component that is included in the length; it must not be less than the value contained in element n+2. A value of -1 denotes the end of the structure. The index is zero-based.</p> <p>The element specified must not be one that is the second or subsequent element in a DTYP_CTL_* sequence of elements.</p> <p>If the value is -1, the length includes all offset data residing at the end of the structure.</p>														
DTYP_CTL_OFFSET	<p>This starts a sequence of four array elements that define data addressed by an offset. The offset resides at this point in the structure, and contains the offset in bytes of the data from the start of the <i>outermost</i> structure in which this component resides. The data addressed by the offset must occupy storage following the fixed part of the structure. The data may be scalar data or array data.</p> <p>The following describes the possible elements:</p> <table><tr><td>n</td><td>DTYP_CTL_OFFSET</td></tr><tr><td>n+1</td><td>data type of the structure component that contains the offset (must be a suitable unsigned numeric data type).</td></tr><tr><td>n+2</td><td>data type of offset data.</td></tr><tr><td>n+3</td><td>minus the number of elements in the array (for an array of fixed size), or the index of the element in <i>types</i> corresponding to the structure component that contains the number of elements in the array being defined; this component must have a suitable numeric data type; the array-size element may occur earlier or later in the structure. This index is zero-based.</td></tr></table> <p>A value of -1 indicates that the data is not an array.</p> <p>This starts a sequence of three array elements that define a pointer to an array. The pointer resides at this point in the structure, and the array resides elsewhere. The array can have a fixed or variable number of elements.</p> <p>The following describes the possible elements:</p> <table><tr><td>n</td><td>DTYP_CTL_PARRAY</td></tr><tr><td>n+1</td><td>data type of array data.</td></tr><tr><td>n+2</td><td>minus the number of elements in the</td></tr></table>		n	DTYP_CTL_OFFSET	n+1	data type of the structure component that contains the offset (must be a suitable unsigned numeric data type).	n+2	data type of offset data.	n+3	minus the number of elements in the array (for an array of fixed size), or the index of the element in <i>types</i> corresponding to the structure component that contains the number of elements in the array being defined; this component must have a suitable numeric data type; the array-size element may occur earlier or later in the structure. This index is zero-based.	n	DTYP_CTL_PARRAY	n+1	data type of array data.	n+2	minus the number of elements in the
n	DTYP_CTL_OFFSET															
n+1	data type of the structure component that contains the offset (must be a suitable unsigned numeric data type).															
n+2	data type of offset data.															
n+3	minus the number of elements in the array (for an array of fixed size), or the index of the element in <i>types</i> corresponding to the structure component that contains the number of elements in the array being defined; this component must have a suitable numeric data type; the array-size element may occur earlier or later in the structure. This index is zero-based.															
n	DTYP_CTL_PARRAY															
n+1	data type of array data.															
n+2	minus the number of elements in the															
DTYP_CTL_PARRAY																

array (for an array of fixed size) or the index of the element in *types* corresponding to the structure component that contains the number of elements in the array being defined. This component must have a suitable numeric data type. The array-size element may occur earlier or later in the structure. The index is zero-based.

WinRegisterUserDatatype Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinRegisterUserDatatype - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

datatype ([LONG](#)) - input
Data type code to be defined.

This must not be less than DTYP_USER, and must not have been defined previously.

count ([LONG](#)) - input
Number of elements.

Must not be less than one.

types ([PLONG](#)) - input
Data type codes of structure components.

Valid data types are the system-defined data types and their pointer equivalents, application-defined data types and their pointer equivalents, and control data types. Note that not all of the data types that occur in the CPI can be specified on this function.

A control data type is followed by one or more entries in the *types* array that are interpreted in a special way. Control data types allow arrays, offsets, and lengths to be defined.

Pointer to an item of data type DTYP_*, where DTYP_* is one of the data types in the preceding lists. The value of a pointer data type is the value of the corresponding non-pointer data type prefixed with a minus to make it negative.

Minimum Application Data Type:

DTYP_USER

Minimum value for application-defined non-pointer data types.

Control Data Type:

DTYP_CTL_ARRAY

This starts a sequence of three array elements that define an array; the array resides in the structure being defined, and may have a fixed number of elements or a variable number of elements.

The following describes the possible elements:

n	DTYP_CTL_ARRAY
n +1	data type of array data.
n+2	minus the number of elements in the array (for an array of fixed size), or the index of the element in <i>types</i> corresponding to the structure component which contains the number of elements in the array being defined. This component must have a suitable numeric data type. The array-size element must precede element "n" in <i>types</i> . The index is zero-based.

DTYP_CTL_LENGTH

This starts a sequence of four array elements that define a structure component containing the length of part or all of the structure. The length component resides at this point in the structure.

The following describes the possible elements:	
n	DYP_CTL_LENGTH
n+1	data type of structure component that contains the length (must be a suitable numeric data type).
n+2	the index of the element in <i>types</i> corresponding to the first structure component that is included in the length; a value of -1 denotes the start of the structure. This index is zero-based. The element specified must not be one that is the second or subsequent element in a DTYP_CTL_* sequence of elements.
N+3	the index of the element in <i>types</i> corresponding to the last structure component that is included in the length; it must not be less than the value contained in element n+2. A value of -1 denotes the end of the structure. The index is zero-based. The element specified must not be one that is the second or subsequent element in a DTYP_CTL_* sequence of elements. If the value is -1, the length includes all offset data residing at the end of the structure.

DTYP_CTL_OFFSET

This starts a sequence of four array elements that define data addressed by an offset. The offset resides at this point in the structure, and contains the offset in bytes of the data from the start of the *outermost* structure in which this component resides. The data addressed by the offset must occupy storage following the fixed part of the structure. The data may be scalar data or array data.

The following describes the possible elements:	
n	DTYP_CTL_OFFSET
n+1	data type of the structure component that contains the offset (must be a suitable unsigned numeric data type).
n+2	data type of offset data.
n+3	minus the number of elements in the array (for an array of fixed size), or the index of the element in <i>types</i> corresponding to the structure component that contains the number of elements in the array being defined; this component must have a suitable numeric data type; the array-size element may occur earlier or later in the structure. This index is zero-based. A value of -1 indicates that the data is not an array.

DTYP_CTL_PARRAY

This starts a sequence of three array elements that define a pointer to an array. The pointer resides at this point in the structure, and the array resides elsewhere. The array can have a fixed or variable number of elements.

The following describes the possible elements:
n DTYP_CTL_PARRAY

n+1	data type of array data.
n+2	minus the number of elements in the array (for an array of fixed size) or the index of the element in <i>types</i> corresponding to the structure component that contains the number of elements in the array being defined. This component must have a suitable numeric data type. The array-size element may occur earlier or later in the structure. The index is zero-based.

rc (**BOOL**) - returns
 Success indicator.

TRUE Successful completion

FALSE Error occurred.

WinRegisterUserDatatype - Remarks

This function has no effect unless the [RegisterUserHook](#) hook has been set.

The value to be used should be obtained by calling [WinAddAtom](#) with the handle of the system atom manager, and subtracting DTYP_ATOM_OFFSET from the result.

[WinAddAtom](#) is guaranteed to return values in the range 0xC000 to 0xFFFF.

When a data type is defined using this function, a definition for the corresponding pointer data type is automatically established.

WinRegisterUserDatatype - Errors

Possible returns from [WinGetLastError](#)

PMERR_DATATYPE_TOO_SMALL (0x1048)
 The datatype specified was too small.

PMERR_DATATYPE_NOT_UNIQUE (0x1046)
 An attempt to register a datatype failed because it is not unique.

PMERR_ARRAY_TOO_SMALL (0x103E)
 The array specified was too small.

PMERR_DATATYPE_ENTRY_NOT_NUM (0x1043)
 The datatype entry specified was not numerical.

PMERR_DATATYPE_ENTRY_NOT_OFF (0x1044)
 The datatype entry specified was not an offset.

PMERR_DATATYPE_ENTRY_BAD_INDEX (0x103F)
 An invalid datatype entry index was specified.

PMERR_DATATYPE_ENTRY_CTL_MISS (0x1041)
 The datatype entry control was missing.

PMERR_DATATYPE_ENTRY_CTL_BAD (0x1040)
 An invalid datatype entry control was specified.

WinRegisterUserMsg

WinRegisterUserMsg - Syntax

This function registers a user message and defines its parameters.

```
#define INCL_WINMESSAGEGR /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
ULONG    msgid;         /* Message identifier. */
LONG     datatype1;     /* Data type of message parameter 1. */
LONG     dir1;          /* Direction of message parameter 1. */
LONG     datatype2;     /* Data type of message parameter 2. */
LONG     dir2;          /* Direction of message parameter 2. */
LONG     datatypeR;     /* Data type of message reply. */
BOOL     rc;            /* Success indicator. */

rc = WinRegisterUserMsg(hab, msgid, datatype1,
                        dir1, datatype2, dir2, datatypeR);
```

WinRegisterUserMsg Parameter - hab

hab (**HAB**) - input
Anchor-block handle.

WinRegisterUserMsg Parameter - msgid

msgid (**ULONG**) - input
Message identifier.

This must not be less than WM_USER, and must not have been defined previously.

WinRegisterUserMsg Parameter - datatype1

datatype1 ([LONG](#)) - input
Data type of message parameter 1.

Valid data types are listed below. For data types that are shorter than 4 bytes, the data must be placed in the least-significant bytes, with the most significant bytes nullified (unsigned data types) or signed-extended (signed data types).

DTYP_BIT16	See BIT16 data type.
DTYP_BIT32	See BIT32 data type.
DTYP_BIT8	See BIT8 data type.
DTYP_BOOL	See BOOL data type.
DTYP_LONG	See LONG data type.
DTYP_SHORT	See SHORT data type.
DTYP_UCHAR	See UCHAR data type.
DTYP_ULONG	See ULONG data type.
DTYP_USHORT	See USHORT data type.
DTYP_P*	A pointer to a system data type. Note that not all of the system data types that exist in the CPI are valid.
< -DTYP_USER	A pointer to a user data type. The user data type must have already been defined via WinRegisterUserDatatype .

WinRegisterUserMsg Parameter - dir1

dir1 ([LONG](#)) - input
Direction of message parameter 1.

If the message parameter is a pointer, the direction values listed below apply to the *contents* of the storage location pointed at, as well as to the message parameter itself.

RUM_IN	Input parameter (inspected by the recipient of the message, but not altered)
RUM_OUT	Output parameter (altered by the recipient of the message, without inspecting its value first)
RUM_INOUT	Input/output parameter (inspected by the recipient of the message, and then altered).

WinRegisterUserMsg Parameter - datatype2

datatype2 (**LONG**) - input
Data type of message parameter 2.

See the description of *datatype1*.

WinRegisterUserMsg Parameter - dir2

dir2 (**LONG**) - input
Direction of message parameter 2.

See the description of *dir1*.

WinRegisterUserMsg Parameter - datatypeper

datatypeper (**LONG**) - input
Data type of message reply.

See the description of *datatype1*. The message reply is always an output parameter.

WinRegisterUserMsg Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinRegisterUserMsg - Parameters

hab (**HAB**) - input
Anchor-block handle.

msgid (**ULONG**) - input
Message identifier.

This must not be less than WM_USER, and must not have been defined previously.

datatype1 (**LONG**) - input
Data type of message parameter 1.

Valid data types are listed below. For data types that are shorter than 4 bytes, the data must be placed in the least-significant bytes, with the most significant bytes nullified (unsigned data types) or signed-extended (signed data types).

DTYP_BIT16	See BIT16 data type.
DTYP_BIT32	See BIT32 data type.
DTYP_BIT8	See BIT8 data type.
DTYP_BOOL	See BOOL data type.
DTYP_LONG	See LONG data type.
DTYP_SHORT	See SHORT data type.
DTYP_UCHAR	See UCHAR data type.
DTYP_ULONG	See ULONG data type.
DTYP_USHORT	See USHORT data type.
DTYP_P*	A pointer to a system data type. Note that not all of the system data types that exist in the CPI are valid.
< -DTYP_USER	A pointer to a user data type. The user data type must have already been defined via WinRegisterUserDatatype .

dir1 ([LONG](#)) - input

Direction of message parameter 1.

If the message parameter is a pointer, the direction values listed below apply to the *contents* of the storage location pointed at, as well as to the message parameter itself.

RUM_IN	Input parameter (inspected by the recipient of the message, but not altered)
RUM_OUT	Output parameter (altered by the recipient of the message, without inspecting its value first)
RUM_INOUT	Input/output parameter (inspected by the recipient of the message, and then altered).

datatype2 ([LONG](#)) - input

Data type of message parameter 2.

See the description of *datatype1*.

dir2 ([LONG](#)) - input

Direction of message parameter 2.

See the description of *dir1*.

datatypeper ([LONG](#)) - input

Data type of message reply.

See the description of *datatype1*. The message reply is always an output parameter.

rc ([BOOL](#)) - returns

Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinRegisterUserMsg - Remarks

This function has no effect unless the [RegisterUserHook](#) hook, which is invoked by this function, has been set.

It is an error to attempt to register the same message identifier more than once within a single OS/2 process.

WinRegisterUserMsg - Errors

Possible returns from [WinGetLastError](#)

PMERR_MSGID_TOO_SMALL (0x104F)
The message identifier specified is too small.

PMERR_DATATYPE_INVALID (0x1045)
An invalid datatype was specified.

PMERR_DATATYPE_TOO_LONG (0x1047)
The datatype specified was too long.

WinRegisterUserMsg - Example Code

This example uses the WinRegisterUserMsg call to register a user-defined message and define its parameters.

```
#define INCL_WINMESSAGEGR
```

```

#define INCL_WINTYPES
#include <OS2.H>
#define WM_MY_MESSAGE WM_USER + 11

HAB hab;

WinRegisterUserMessage(hab,
    WM_MY_MESSAGE,
    DTYP_BIT16, /* param1 is a USHORT */
    RUM_INOUT, /* param1 is input/output */
    DTYP_BIT16, /* param2 is a USHORT */
    RUM_INOUT, /* param2 is input/output */
    DTYP_BIT16); /* reply is a USHORT */

```

WinReleaseHook

WinReleaseHook - Syntax

This function releases an application hook from a hook chain.

```

#define INCL_WINHOOKS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
HMQ      hmq;          /* Handle of message queue from which the hook is to be released. */
LONG     lHook;        /* Type of hook chain. */
PFN      pAddress;     /* Address of the hook routine. */
HMODULE  Module;       /* Module handle. */
BOOL     rc;           /* Success indicator. */

rc = WinReleaseHook(hab, hmq, lHook, pAddress,
    Module);

```

WinReleaseHook Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinReleaseHook Parameter - hmq

hmq ([HMQ](#)) - input
Handle of message queue from which the hook is to be released.

HMQ_CURRENT
The hook is released from the message queue associated with the current thread (calling thread).

NULLHANDLE
The hook is released from the system hook chain.

WinReleaseHook Parameter - IHook

IHook ([LONG](#)) - input
Type of hook chain.

This parameter can have one of the following HK_* values:

HK_CHECKMSGFILTER
See [CheckMsgFilterHook](#).

HK_CODEPAGECHANGED
See [CodePageChangedHook](#).

HK_DESTROYWINDOW
See [DestroyWindowHook](#).

HK_FINDWORD
See [FindWordHook](#).

HK_FLUSHBUF
See [FlushBufHook](#).

HK_HELP
See [HelpHook](#).

HK_INPUT
See [InputHook](#).

HK_JOURNALPLAYBACK
See [JournalPlaybackHook](#).

HK_JOURNALRECORD
See [JournalRecordHook](#).

HK_LOADER
See [LoaderHook](#).

HK_LOCKUP
See [LockupHook](#).

HK_MSGCONTROL
See [MsgControlHook](#).

HK_MSGFILTER
See [MsgFilterHook](#).

HK_MSGINPUT
See [MsgInputHook](#).

HK_PLIST_ENTRY
See [ProgramListEntryHook](#).

HK_PLIST_EXIT
See [ProgramListExitHook](#).

HK_REGISTERUSERMSG
See [RegisterUserHook](#).

HK_SENDMSG
See [SendMsgHook](#).

HK_WINDOWDC

See [WindowDCHook](#)

WinReleaseHook Parameter - pAddress

pAddress ([PFN](#)) - input

Address of the hook routine.

WinReleaseHook Parameter - Module

Module ([HMODULE](#)) - input

Module handle.

NULLHANDLE

The hook procedure is in the application's .EXE file.

Module

This is the module that contains the application procedure, as returned by the DosLoadModule or DosQueryModuleHandle call.

WinReleaseHook Return Value - rc

rc ([BOOL](#)) - returns

Success indicator.

TRUE

Successful completion

FALSE

Error occurred.

WinReleaseHook - Parameters

hab ([HAB](#)) - input

Anchor-block handle.

hmq ([HMQ](#)) - input

Handle of message queue from which the hook is to be released.

HMQ_CURRENT

The hook is released from the message queue associated with the current thread (calling thread).

NULLHANDLE

The hook is released from the system hook chain.

IHook ([LONG](#)) - input

Type of hook chain.

This parameter can have one of the following HK_* values:

HK_CHECKMSGFILTER	See CheckMsgFilterHook .
HK_CODEPAGECHANGED	See CodePageChangedHook .
HK_DESTROYWINDOW	See DestroyWindowHook .
HK_FINDWORD	See FindWordHook .
HK_FLUSHBUF	See FlushBufHook .
HK_HELP	See HelpHook .
HK_INPUT	See InputHook .
HK_JOURNALPLAYBACK	See JournalPlaybackHook .
HK_JOURNALRECORD	See JournalRecordHook .
HK_LOADER	See LoaderHook .
HK_LOCKUP	See LockupHook .
HK_MSGCONTROL	See MsgControlHook .
HK_MSGFILTER	See MsgFilterHook .
HK_MSGINPUT	See MsgInputHook .
HK_PLIST_ENTRY	See ProgramListEntryHook .
HK_PLIST_EXIT	See ProgramListExitHook .
HK_REGISTERUSERMSG	See RegisterUserHook .
HK_SENDMSG	See SendMsgHook .
HK_WINDOWDC	See WindowDCHook .

pAddress ([PFN](#)) - input
Address of the hook routine.

Module ([HMODULE](#)) - input
Module handle.

NULLHANDLE	The hook procedure is in the application's .EXE file.
Module	This is the module that contains the application procedure, as returned by the DosLoadModule or DosQueryModuleHandle call.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinReleaseHook - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HMQ (0x1002)
An invalid message-queue handle was specified.

PMERR_PARAMETER_OUT_OF_RANGE (0x1003)
The value of a parameter was not within the defined valid range for that parameter.

WinReleaseHook - Related Functions

Related Functions

- [WinCallMsgFilter](#)
- [WinReleaseHook](#)

WinReleaseHook - Example Code

This example uses the WinReleaseHook call to release a hook that records user-input messages from the application queue.

```
#define INCL_WINHOOKS
#include <OS2.H>

void RecordHook(HAB hab, PQMSG pqmsg);

samp()
{
    HAB hab;

    WinSetHook(hab,
               HMQ_CURRENT,
               HK_JOURNALRECORD,
               (PFN)RecordHook,
               (HMODULE)0); /* hook is into application queue. */

    WinReleaseHook(hab,
                   HMQ_CURRENT,
                   HK_JOURNALRECORD,
                   (PFN)RecordHook,
                   (HMODULE)0); /* hook is into application queue, */

}

/* This hook records user-input messages. */
void RecordHook(HAB hab, PQMSG pqmsg)
{
    /* ... */
}
```

WinReleasePS

WinReleasePS - Syntax

This method releases a cache presentation space obtained using the [WinGetPS](#), the [WinGetScreenPS](#), or the [WinGetClipPS](#) call.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HPS      hps; /* Handle of the cache presentation space to release, as returned by the WinGetPS, the WinGetScr
BOOL      rc; /* Success indicator. */

rc = WinReleasePS(hps);
```

WinReleasePS Parameter - hps

hps ([HPS](#)) - input
Handle of the cache presentation space to release, as returned by the [WinGetPS](#), the [WinGetScreenPS](#), or the [WinGetClipPS](#) function.

WinReleasePS Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion.
FALSE	Error occurred.

WinReleasePS - Parameters

hps ([HPS](#)) - input

Handle of the cache presentation space to release, as returned by the [WinGetPS](#), the [WinGetScreenPS](#), or the [WinGetClipPS](#) function.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion.
FALSE	Error occurred.

WinReleasePS - Remarks

Only cache presentation spaces can be released using this method, after which the presentation space is returned to the cache to be used again. The presentation-space handle should not be used following this call.

WinRemovePresParam

WinRemovePresParam - Syntax

This function removes a presentation parameter associated with the window *hwnd*.

```

#define INCL_WINSYS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwnd;          /* Window handle whose presentation is to be change. */
ULONG    idAttrType;    /* Type of presentation parameter attribute to be removed. */
BOOL     rc;            /* Success indicator. */

rc = WinRemovePresParam(hwnd, idAttrType);

```

WinRemovePresParam Parameter - hwnd

hwnd (**HWND**) - input
 Window handle whose presentation is to be change.

WinRemovePresParam Parameter - idAttrType

idAttrType (ULONG) - input

Type of presentation parameter attribute to be removed.

This parameter can be set to one of the following system-defined presentation parameter attribute types or an application-defined type.

PP_FOREGROUND_COLOR

Foreground color (in RGB) attribute.

PP_BACKGROUND_COLOR

Background color (in RGB) attribute.

PP_FOREGROUND_COLOR_INDEX

Foreground color index attribute.

PP_BACKGROUND_COLOR_INDEX

Background color index attribute.

PP_HILITE_FOREGROUND_COLOR

Highlighted foreground color (in RGB) attribute, for example for selected menu items.

PP_HILITE_BACKGROUND_COLOR

Highlighted background color (in RGB) attribute.

PP_HILITE_FOREGROUND_COLOR_INDEX

Highlighted foreground color index attribute.

PP_HILITE_BACKGROUND_COLOR_INDEX

Highlighted background color index attribute.

PP_DISABLED_FOREGROUND_COLOR

Disabled foreground color (in RGB) attribute.

PP_DISABLED_BACKGROUND_COLOR

Disabled background color (in RGB) attribute.

PP_DISABLED_FOREGROUND_COLOR_INDEX

Disabled foreground color index attribute.

PP_DISABLED_BACKGROUND_COLOR_INDEX

Disabled background color index attribute.

PP_BORDER_COLOR

Border color (in RGB) attribute.

PP_BORDER_COLOR_INDEX

Border color index attribute.

PP_FONT_NAME_SIZE

Font name and size attribute.

PP_ACTIVE_COLOR

Active color value of data type RGB.

PP_ACTIVE_COLOR_INDEX

Active color index value of data type LONG.

PP_INACTIVE_COLOR

Inactive color value of data type RGB.

PP_INACTIVE_COLOR_INDEX

Inactive color index value of data type LONG.

PP_ACTIVE_TEXT_FGND_COLOR

Active text foreground color value of data type RGB.

PP_ACTIVE_TEXT_FGND_COLOR_INDEX

Active text foreground color index value of data type LONG.

PP_ACTIVE_TEXT_BGND_COLOR

Active text background color value of data type [RGB](#).

PP_ACTIVETEXTBGNDINDEX
Active text background color index value of data type [LONG](#).

PP_INACTIVETEXTFGNDCOLOR
Inactive text foreground color value of data type [RGB](#).

PP_INACTIVETEXTFGNDINDEX
Inactive text foreground color index value of data type [LONG](#).

PP_INACTIVETEXTBGNDCOLOR
Inactive text background color value of data type [RGB](#).

PP_INACTIVETEXTBGNDINDEX
Inactive text background color index value of data type [LONG](#).

PP_SHADOW
Changes the color used for drop shadows on certain controls.

PP_USER
This is a user-defined presentation parameter.

WinRemovePresParam Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE
Successful completion

FALSE
Error occurred.

WinRemovePresParam - Parameters

hwnd ([HWND](#)) - input
Window handle whose presentation is to be change.

idAttrType ([ULONG](#)) - input
Type of presentation parameter attribute to be removed.

This parameter can be set to one of the following system-defined presentation parameter attribute types or an application-defined type.

PP_FOREGROUND
Foreground color (in [RGB](#)) attribute.

PP_BACKGROUND
Background color (in [RGB](#)) attribute.

PP_FOREGROUNDINDEX
Foreground color index attribute.

PP_BACKGROUNDINDEX
Background color index attribute.

PP_HILITEFOREGROUND
Highlighted foreground color (in [RGB](#)) attribute, for example for selected menu items.

PP_HILITEBACKGROUNDCOLOR
Highlighted background color (in [RGB](#)) attribute.

PP_HILITEFOREGROUNDCOLORINDEX
Highlighted foreground color index attribute.

PP_HILITEBACKGROUNDINDEX
Highlighted background color index attribute.

PP_DISABLEDFOREGROUNDCOLOR
Disabled foreground color (in [RGB](#)) attribute.

PP_DISABLEDBACKGROUNDINDEX
Disabled background color (in [RGB](#)) attribute.

PP_DISABLEDFOREGROUNDCOLORINDEX
Disabled foreground color index attribute.

PP_DISABLEDBACKGROUNDINDEX
Disabled background color index attribute.

PP_BORDERCOLOR
Border color (in [RGB](#)) attribute.

PP_BORDERINDEX
Border color index attribute.

PP_FONTNAME
Font name and size attribute.

PP_ACTIVECOLOR
Active color value of data type [RGB](#).

PP_ACTIVEINDEX
Active color index value of data type [LONG](#).

PP_INACTIVECOLOR
Inactive color value of data type [RGB](#).

PP_INACTIVEINDEX
Inactive color index value of data type [LONG](#).

PP_ACTIVETEXTFGNDINDEX
Active text foreground color value of data type [RGB](#).

PP_ACTIVETEXTFGNDINDEX
Active text foreground color index value of data type [LONG](#).

PP_ACTIVETEXTBGNDINDEX
Active text background color value of data type [RGB](#).

PP_ACTIVETEXTBGNDINDEX
Active text background color index value of data type [LONG](#).

PP_INACTIVETEXTFGNDINDEX
Inactive text foreground color value of data type [RGB](#).

PP_INACTIVETEXTFGNDINDEX
Inactive text foreground color index value of data type [LONG](#).

PP_INACTIVETEXTBGNDINDEX
Inactive text background color value of data type [RGB](#).

PP_INACTIVETEXTBGNDINDEX
Inactive text background color index value of data type [LONG](#).

PP_SHADOW
Changes the color used for drop shadows on certain controls.

PP_USER
This is a user-defined presentation parameter.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinRemovePresParam - Remarks

When a presentation parameter is removed, a [WM_PRESPARAMCHANGED](#) message is sent to all windows owned by the window calling the [WinSetPresParam](#) function. (See also [WinSetPresParam](#) and [WinQueryPresParam](#).)

WinRemovePresParam - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinRemoveSwitchEntry

WinRemoveSwitchEntry - Syntax

This function removes a specified entry from the Window List.

```
#define INCL_WINSWITCHLIST /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HSWITCH    hswitchSwitch; /* Switch-list (Window List) entry handle. */
ULONG      usRetCode;     /* Success indicator. */

usRetCode = WinRemoveSwitchEntry(hswitchSwitch);
```

WinRemoveSwitchEntry Parameter - hswitchSwitch

hswitchSwitch ([HSWITCH](#)) - input
Switch-list (Window List) entry handle.

WinRemoveSwitchEntry Return Value - usRetCode

usRetCode ([ULONG](#)) - returns
Success indicator.

0	Successful completion
Other	Error occurred.

WinRemoveSwitchEntry - Parameters

hswitchSwitch ([HSWITCH](#)) - input
Switch-list (Window List) entry handle.

usRetCode ([ULONG](#)) - returns
Success indicator.

0	Successful completion
Other	Error occurred.

WinRemoveSwitchEntry - Remarks

An application that uses the operating system effectively should, at least, add its main window to the Window List when it starts, and remove it from the Window List when it stops.

Window List entries for non-OS/2 applications cannot be removed using this function. These entries are removed automatically by the system when the session they occupy terminates.

Note: This function and the [WinCreateSwitchEntry](#) and [WinAddSwitchEntry](#) functions are not required if the main window is created with the frame style FCF_TASKLIST or FCF_STANDARD, as these styles automatically update the Window List when the main window is created, destroyed, or its title changes.

WinRemoveSwitchEntry - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_SWITCH_HANDLE (0x1202)
An invalid Window List entry handle was specified.

PMERR_INVALID_WINDOW (0x1206)
The window specified with a Window List call is not a valid frame window.

WinRemoveSwitchEntry - Related Functions

Related Functions

- [WinAddSwitchEntry](#)

WinReplaceObjectClass

WinReplaceObjectClass - Syntax

The WinReplaceObjectClass function replaces a registered class with another registered class. If *fReplace* is FALSE, *pOldClassName* will revert back to its original definition.

```

#define INCL_WINWORKPLACE
#include <os2.h>

PSZ      pOldClassName; /* Pointer to class name. */
PSZ      pNewClassName; /* Pointer to new class name. */
BOOL     fReplace;      /* Function replacement flag. */
BOOL     rc;             /* Success indicator. */

rc = WinReplaceObjectClass(pOldClassName,
    pNewClassName, fReplace);

```

WinReplaceObjectClass Parameter - pOldClassName

pOldClassName (**PSZ**) - input
 Pointer to class name.

A pointer to a zero-terminated string which contains the name of the object class being replaced by *pNewClassName* in the workplace.

WinReplaceObjectClass Parameter - pNewClassName

pNewClassName (**PSZ**) - input
 Pointer to new class name.

A pointer to a zero-terminated string which contains the name of the object class replacing the *pOldClassName* class.

WinReplaceObjectClass Parameter - fReplace

fReplace (**BOOL**) - input
 Function replacement flag.

TRUE
 Replace the function of class *pOldClassName* with the function of the class *pNewClassName*.

FALSE
 Undo the replacement of the *pOldClassName* with *pNewClassName* by restoring the *pOldClassName* back to its original functionality.

WinReplaceObjectClass Return Value - rc

rc (**BOOL**) - returns
 Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinReplaceObjectClass - Parameters

pOldClassName ([PSZ](#)) - input
Pointer to class name.

A pointer to a zero-terminated string which contains the name of the object class being replaced by *pNewClassName* in the workplace.

pNewClassName ([PSZ](#)) - input
Pointer to new class name.

A pointer to a zero-terminated string which contains the name of the object class replacing the *pOldClassName* class.

fReplace ([BOOL](#)) - input
Function replacement flag.

TRUE	Replace the function of class <i>pOldClassName</i> with the function of the class <i>pNewClassName</i> .
FALSE	Undo the replacement of the <i>pOldClassName</i> with <i>pNewClassName</i> by restoring the <i>pOldClassName</i> back to its original functionality.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinReplaceObjectClass - Remarks

The class specified by *pNewClassName* must be a descendant of the class specified by *pOldClassName*, otherwise an error will be returned. Replacing an object is useful if it is desired to modify the behavior of objects which are instances of the class *pOldClassName* and which are not aware of the class *pNewClassName*.

WinRequestMutexSem

WinRequestMutexSem - Syntax

WinRequestMutexSem requests ownership of a mutex semaphore or waits for a Presentation Manager message.

```
#define INCL_WINMESSAGEGR
#include <os2.h>

HMTX      hmtx;          /* The handle of the mutex semaphore to request. */
ULONG     ulTimeout;     /* Time-out in milliseconds. */
APIRET    ulrc;          /* Return Code. */

ulrc = WinRequestMutexSem(hmtx, ulTimeout);
```

WinRequestMutexSem Parameter - hmtx

hmtx (**HMTX**) - input

The handle of the mutex semaphore to request.

WinRequestMutexSem Parameter - ulTimeout

ulTimeout (**ULONG**) - input

Time-out in milliseconds.

This is the maximum amount of time the user wants to allow the thread to be blocked.

This parameter can also have the following values:

SEM_IMMEDIATE_RETURN (0)

WinRequestMutexSem returns immediately without blocking the calling thread.

SEM_INDEFINITE_WAIT (-1)

WinRequestMutexSem blocks the calling thread indefinitely.

WinRequestMutexSem Return Value - ulrc

ulrc ([APIRET](#)) - returns
Return Code.

WinRequestMutexSem returns the following values:

0	NO_ERROR
6	ERROR_INVALID_HANDLE
95	ERROR_INTERRUPT
103	ERROR_TOO_MANY_SEM_REQUESTS
105	ERROR_SEM_OWNER_DIED
640	ERROR_TIMEOUT

WinRequestMutexSem - Parameters

hmtx ([HMTX](#)) - input
The handle of the mutex semaphore to request.

ulTimeout ([ULONG](#)) - input
Time-out in milliseconds.

This is the maximum amount of time the user wants to allow the thread to be blocked.

This parameter can also have the following values:

SEM_IMMEDIATE_RETURN (0)	WinRequestMutexSem returns immediately without blocking the calling thread.
SEM_INDEFINITE_WAIT (-1)	WinRequestMutexSem blocks the calling thread indefinitely.

ulrc ([APIRET](#)) - returns
Return Code.

WinRequestMutexSem returns the following values:

0	NO_ERROR
6	ERROR_INVALID_HANDLE
95	ERROR_INTERRUPT
103	ERROR_TOO_MANY_SEM_REQUESTS
105	ERROR_SEM_OWNER_DIED
640	ERROR_TIMEOUT

WinRequestMutexSem - Remarks

WinRequestMutexSem is similar to DosRequestMutexSem and requests ownership of a mutex semaphore or waits for a window message sent by the WinSendMsg function from another thread to be received.

This function can be called by any thread in the process that created the semaphore. Threads in other processes can also call this function, but they must first gain access to the semaphore by issuing DosOpenMutexSem.

Since the processing of a window message may take longer than the value specified by the *ulTimeout* parameter, this function may not return within the time specified by that value.

WinRequestMutexSem - Related Functions

Related Functions

- [WinSendMsg](#)
- [WinPostMsg](#)

WinRequestMutexSem - Example Code

This example requests ownership of a mutex semaphore. Assume that the handle of the semaphore has been placed into *hmtx* already.

ulTimeout is the number of milliseconds that the calling thread will wait for ownership of the mutex semaphore. If the specified mutex semaphore is not released during this time interval, the calling thread does not receive ownership of it.

```
#define INCL_DOSSEMAPHORES /* Semaphore values */
#define INCL_WINMESSAGEGR

#include <os2.h>
#include <stdio.h>

#ifndef ERROR_TIMEOUT
#define ERROR_TIMEOUT 640
#define ERROR_INTERRUPT 95
#endif

HMTX hmtx; /* Mutex semaphore handle */
ULONG ulTimeout; /* Number of milliseconds to wait */
ULONG rc; /* Return code */

ulTimeout = 60000; /* Wait for a maximum of 1 minute */

rc = WinRequestMutexSem(hmtx, ulTimeout);

if (rc == ERROR_TIMEOUT)
{
    printf("WinRequestMutexSem call timed out");
    return;
}

if (rc == ERROR_INTERRUPT)
{
    printf("WinRequestMutexSem call was interrupted");
    return;
}

if (rc != 0)
{
    printf("WinRequestMutexSem error: return code = %ld", rc);
    return;
}
```

WinRestartSOMDD

WinRestartSOMDD - Syntax

This function starts the DSOM daemon.

```
#define INCL_WPCLASS
#include <os2.h>

BOOL      fAction; /* Flag indicating action to perform on the DSOM daemon. */
APIRET    rc;      /* Return code. */

rc = WinRestartSOMDD(fAction);
```

WinRestartSOMDD Parameter - fAction

fAction ([BOOL](#)) - input
Flag indicating action to perform on the DSOM daemon.

TRUE	Start the DSOM daemon.
FALSE	Stop the DSOM daemon.

WinRestartSOMDD Return Value - rc

rc ([APIRET](#)) - returns
Return code.

PMERR_OK (0x0000)	Successfully invoked.
PMERR_WPDSEVER_IS_ACTIVE (0x1056)	The Workplace Shell DSOM Server is active and running. It cannot stop the DSOM daemon until the Workplace Shell DSOM Server has stopped.

PMERR_SOMDD_IS_ACTIVE (0x1058)

The DSOM daemon has been started by the Workplace Shell process and is active and running; therefore, it cannot be started again.

PMERR_SOMDD_NOT_STARTED (0x1059)

The DSOM daemon failed to start. It might be active in another process.

WinRestartSOMDD - Parameters

fAction ([BOOL](#)) - input

Flag indicating action to perform on the DSOM daemon.

TRUE

Start the DSOM daemon.

FALSE

Stop the DSOM daemon.

rc ([APIRET](#)) - returns

Return code.

PMERR_OK (0x0000)

Successfully invoked.

PMERR_WPDSEVER_IS_ACTIVE (0x1056)

The Workplace Shell DSOM Server is active and running. It cannot stop the DSOM daemon until the Workplace Shell DSOM Server has stopped.

PMERR_SOMDD_IS_ACTIVE (0x1058)

The DSOM daemon has been started by the Workplace Shell process and is active and running; therefore, it cannot be started again.

PMERR_SOMDD_NOT_STARTED (0x1059)

The DSOM daemon failed to start. It might be active in another process.

WinRestartSOMDD - Remarks

This function starts the DSOM daemon in the Workplace Shell process as a background process invisible to the users. The status of the daemon can be determined at any time by calling [WinIsSOMDDReady](#).

Note: This function requires that the PM Shell is up and running.

WinRestartWPDServer

WinRestartWPDServer - Syntax

This function starts the Workplace Shell DSOM server.

```
#define INCL_WPCLASS
#include <os2.h>

BOOL      fAction; /* Flag indicating the action to perform on the Workplace Shell DSOM server. */
APIRET    rc;      /* Return code. */

rc = WinRestartWPDServer(fAction);
```

WinRestartWPDServer Parameter - fAction

fAction (BOOL) - input

Flag indicating the action to perform on the Workplace Shell DSOM server.

TRUE

Start the Workplace Shell DSOM server.

FALSE

Stop the Workplace Shell DSOM server.

WinRestartWPDServer Return Value - rc

rc (APIRET) - returns

Return code.

PMERR_OK (0x0000)

Successfully invoked.

PMERR_WPDSEVER_IS_ACTIVE (0x1056)

The Workplace Shell DSOM server is active and cannot be started again.

PMERR_WPDSEVER_NOT_STARTED (0x1057)

The Workplace Shell DSOM server could not be started, possibly related to a corrupted copy of WPDSRVP.DLL.

Other

Any other non-zero value could indicate that the WPDSRVP.DLL is corrupted or not found.

WinRestartWPDServer - Parameters

fAction (BOOL) - input

Flag indicating the action to perform on the Workplace Shell DSOM server.

TRUE

Start the Workplace Shell DSOM server.

FALSE

Stop the Workplace Shell DSOM server.

rc (APIRET) - returns

Return code.

PMERR_OK (0x0000)

Successfully invoked.

PMERR_WPDSEVER_IS_ACTIVE (0x1056)

The Workplace Shell DSOM server is active and cannot be started again.

PMERR_WPDSEVER_NOT_STARTED (0x1057)

The Workplace Shell DSOM server could not be started, possibly related to a corrupted copy of WPDSRVP.DLL.

Other

Any other non-zero value could indicate that the WPDSRVP.DLL is corrupted or not found.

WinRestartWPDServer - Remarks

This function requires that the DSOM daemon is started first and must be running successfully in order for the Workplace Shell DSOM

server to become ready. The status of the Workplace Shell DSOM server can be obtained at any time using [WinIsWPDServerReady](#). Once the DSOM server is ready, a client Workplace Shell DSOM server application can be executed.

Note: This function requires that the PM Shell is up and running.

WinRestoreWindowPos

WinRestoreWindowPos - Syntax

The WinRestoreWindowPos function will restore the size and position of the window specified by *hwnd* to the state it was in when [WinStoreWindowPos](#) was last called with the same *pAppName* and *pKeyName*.

```
#define INCL_WINWORKPLACE
#include <os2.h>

PSZ      pAppName; /* Pointer to application name. */
PSZ      pKeyName; /* Pointer to key name. */
HWND     hwnd;     /* Window handle of the window to restore. */
BOOL     rc;       /* Success indicator. */

rc = WinRestoreWindowPos(pAppName, pKeyName,
                        hwnd);
```

WinRestoreWindowPos Parameter - pAppName

pAppName ([PSZ](#)) - input

Pointer to application name.

A pointer to a zero-terminated string which contains the application name.

WinRestoreWindowPos Parameter - pKeyName

pKeyName ([PSZ](#)) - input

Pointer to key name.

A pointer to a zero-terminated string which contains the key name.

WinRestoreWindowPos Parameter - hwnd

hwnd ([HWND](#)) - input
Window handle of the window to restore.

WinRestoreWindowPos Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinRestoreWindowPos - Parameters

pAppName ([PSZ](#)) - input
Pointer to application name.

A pointer to a zero-terminated string which contains the application name.

pKeyName ([PSZ](#)) - input
Pointer to key name.

A pointer to a zero-terminated string which contains the key name.

hwnd ([HWND](#)) - input
Window handle of the window to restore.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinRestoreWindowPos - Remarks

This function will also restore presentation parameters which were saved by a previous call to [WinStoreWindowPos](#).

WinSaveObject

WinSaveObject - Syntax

This function is specific to OS/2 Version 3.0 or higher.

This function saves the state of an object.

```
#define INCL_WINWORKPLACE
#include <os2.h>

HOBJECT    hObject; /* Handle of the object to be saved. */
BOOL       fAsync;  /* Asynchronous flag. */
BOOL       rc;      /* Success indicator. */

rc = WinSaveObject(hObject, fAsync);
```

WinSaveObject Parameter - hObject

hObject ([HOBJECT](#)) - input
Handle of the object to be saved.

WinSaveObject Parameter - fAsync

fAsync (BOOL) - input
Asynchronous flag.

TRUE	Calls asynchronous save.
FALSE	Calls synchronous save.

WinSaveObject Return Value - rc

rc (BOOL) - returns
Success indicator.

TRUE	Successful completion.
FALSE	Error occurred.

WinSaveObject - Parameters

hObject (HOBJECT) - input
Handle of the object to be saved.

fAsync (BOOL) - input
Asynchronous flag.

TRUE	Calls asynchronous save.
FALSE	Calls synchronous save.

rc (BOOL) - returns
Success indicator.

TRUE	Successful completion.
FALSE	Error occurred.

WinSaveObject - Remarks

If an asynchronous save is called, the object will be saved on a separate thread ("lazy written"); this is the preferred method for saving. Otherwise, the object is saved on the user interface thread.

Using [HOBJECT](#) for .INI files or files in which an application uses a rename/save/delete sequence is not supported.

WinSaveWindowPos

WinSaveWindowPos - Syntax

This function associates an array of [SWP](#) structures with the process of repositioning a frame window.

```
#define INCL_WINFRAMEMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HSAVEWP    hsvwp; /* Identifier of the frame window repositioning process. */
PSWP       pswp;  /* Array of SWP structures. */
ULONG      cswp;  /* Count of SWP structures. */
BOOL       rc;    /* Success indicator. */

rc = WinSaveWindowPos(hsvwp, pswp, cswp);
```

WinSaveWindowPos Parameter - hsvwp

hsvwp ([HSAVEWP](#)) - input
Identifier of the frame window repositioning process.

This handle is provided in the second parameter of the [WM_ADJUSTFRAMEPOS](#) message.

WinSaveWindowPos Parameter - pswp

pswp ([PSWP](#)) - input
Array of [SWP](#) structures.

WinSaveWindowPos Parameter - cswp

cswp ([ULONG](#)) - input
Count of [SWP](#) structures.

WinSaveWindowPos Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinSaveWindowPos - Parameters

hsvwp ([HSAVEWP](#)) - input
Identifier of the frame window repositioning process.

This handle is provided in the second parameter of the [WM_ADJUSTFRAMEPOS](#) message.

pswp ([PSWP](#)) - input
Array of [SWP](#) structures.

cswp ([ULONG](#)) - input
Count of [SWP](#) structures.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinSaveWindowPos - Remarks

WinScrollWindow

WinScrollWindow - Syntax

This function scrolls the contents of a window rectangle.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HWND      hwnd;          /* Window handle. */
LONG      lDx;            /* Amount of horizontal scroll to the right (in device units). */
LONG      lDy;            /* Amount of vertical scroll upward (in device units). */
PRECTL    prclScroll;     /* Scroll rectangle. */
PRECTL    prclClip;       /* Clip rectangle. */
```

```

HRGN      hrgnUpdateRgn; /* Update region. */
PRECTL    prclUpdate;    /* Update rectangle. */
ULONG     flOptions;      /* Scroll options. */
LONG      lComplexity;    /* Complexity of resulting region/error indicator. */

lComplexity = WinScrollWindow(hwnd, lDx, lDy,
                             prclScroll, prclClip, hrgnUpdateRgn,
                             prclUpdate, flOptions);

```

WinScrollWindow Parameter - hwnd

hwnd ([HWND](#)) - input
Window handle.

WinScrollWindow Parameter - lDx

lDx ([LONG](#)) - input
Amount of horizontal scroll to the right (in device units).

WinScrollWindow Parameter - lDy

lDy ([LONG](#)) - input
Amount of vertical scroll upward (in device units).

WinScrollWindow Parameter - prclScroll

prclScroll ([PRECTL](#)) - input
Scroll rectangle.

If this is NULL, the entire window is scrolled.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) may also be used, if supported by the language.

WinScrollWindow Parameter - prclClip

prclClip ([PRECTL](#)) - input
Clip rectangle.

If not NULL, this defines a clip rectangle that clips the destination of the scroll.

WinScrollWindow Parameter - hrgnUpdateRgn

hrgnUpdateRgn ([HRGN](#)) - input
Update region.

If not NULLHANDLE, this contains the region uncovered by the scroll when returned.

WinScrollWindow Parameter - prclUpdate

prclUpdate ([PRECTL](#)) - in/out
Update rectangle.

If not NULL, this contains the bounding rectangle of the invalid bits uncovered by the scroll when returned.

WinScrollWindow Parameter - flOptions

flOptions ([ULONG](#)) - input
Scroll options.

SW_SCROLLCHILDREN
Unless this is set, child windows are not scrolled. If this is set, and *prclScroll* is NULL, all the child windows are scrolled by *lDx* and *lDy* units. If *prclScroll* is not NULL, only those child windows that intersect *prclScroll* are scrolled.

SW_INVALIDATERGN
The invalid region created as a result of the scroll is added to the update regions of those windows affected. This may result in sending [WM_PAINT](#) messages to CS_SYNCPAINT windows before the call returns.

WinScrollWindow Return Value - lComplexity

lComplexity ([LONG](#)) - returns
Complexity of resulting region/error indicator.

RGN_NULL NULL rectangle invalid
RGN_RECT Simple rectangle invalid
RGN_COMPLEX Complex rectangle invalid

RGN_ERROR
Error.

WinScrollWindow - Parameters

hwnd ([HWND](#)) - input
Window handle.

IDx ([LONG](#)) - input
Amount of horizontal scroll to the right (in device units).

IDy ([LONG](#)) - input
Amount of vertical scroll upward (in device units).

prcIScroll ([PRECTL](#)) - input
Scroll rectangle.

If this is NULL, the entire window is scrolled.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) may also be used, if supported by the language.

prcIClip ([PRECTL](#)) - input
Clip rectangle.

If not NULL, this defines a clip rectangle that clips the destination of the scroll.

hrgnUpdateRgn ([HRGN](#)) - input
Update region.

If not NULLHANDLE, this contains the region uncovered by the scroll when returned.

prcIUpdate ([PRECTL](#)) - in/out
Update rectangle.

If not NULL, this contains the bounding rectangle of the invalid bits uncovered by the scroll when returned.

flOptions ([ULONG](#)) - input
Scroll options.

SW_SCROLLCHILDREN
Unless this is set, child windows are not scrolled. If this is set, and *prcIScroll* is NULL, all the child windows are scrolled by *IDx* and *IDy* units. If *prcIScroll* is not NULL, only those child windows that intersect *prcIScroll* are scrolled.

SW_INVALIDATERGN
The invalid region created as a result of the scroll is added to the update regions of those windows affected. This may result in sending [WM_PAINT](#) messages to CS_SYNCPAINT windows before the call returns.

lComplexity ([LONG](#)) - returns
Complexity of resulting region/error indicator.

RGN_NULL
NULL rectangle invalid
RGN_RECT
Simple rectangle invalid
RGN_COMPLEX
Complex rectangle invalid
RGN_ERROR
Error.

WinScrollWindow - Remarks

This function scrolls the contents of a rectangle defined by *prc/Scroll* in the window *hwnd*, by *IDx* units horizontally and *IDy* units vertically. All coordinates must be in device units.

Clipping takes place on the final image of the scrolling. Even if the scroll rectangle lies outside the clip rectangle, these bits are scrolled, if their destination lies within the intersection of the clip rectangle and the destination rectangle.

This function returns an RGN_* value, indicating the type of invalid region created by the scroll as returned by GpiCombineRegion. RGN_ERROR is returned if *hwnd* is invalid.

Note: If *hwnd* has style WS_CLIPCHILDREN, portions of any child window within the scroll area are scrolled. In this instance, this function must be called with *fOptions* SW_SCROLLCHILDREN.

This is the only function that can be used by a thread to move bits within its own window, because of the critical section nature of window update regions.

Scrolling is fastest without SW_SCROLLCHILDREN and SW_INVALIDATERGN. When scrolling needs to be repeated quickly, do not include the SW_INVALIDATERGN flag and repaint the invalid area if the invalid region is rectangular, otherwise invalidate and update.

If the scrolling is infrequent, include the SW_INVALIDATERGN flag. This function invalidates and updates synchronous-paint windows automatically before returning.

The cursor and the track rectangle are scrolled when they intersect with the scrolled region. Any part of the window's initial update region that intersects the scrolled region is also offset.

WinScrollWindow - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

PMERR_INVALID_FLAG (0x1019)
An invalid bit was set for a parameter. Use constants defined by PM for options, and do not set any reserved bits.

PMERR_HRGN_BUSY (0x2034)
An internal region busy error was detected. The region was locked by one thread during an attempt to access it from another thread.

MRESULT   mresReply; /* Message-return data. */

mresReply = WinSendDlgItemMsg(hwndDlg, idItem,
                              msg, mp1, mp2);
```

WinSendDlgItemMsg Parameter - hwndDlg

hwndDlg (**HWND**) - input
Parent-window handle.

WinSendDlgItemMsg Parameter - idItem

idItem (**ULONG**) - input
Identity of the child window.

It must be greater or equal to 0 and less or equal to 0xFFFF.

WinSendDlgItemMsg Parameter - msg

msg (**ULONG**) - input
Message identity.

WinSendDlgItemMsg Parameter - mp1

mp1 ([MPARAM](#)) - input
Message parameter 1.

WinSendDlgItemMsg Parameter - mp2

mp2 ([MPARAM](#)) - input
Message parameter 2.

WinSendDlgItemMsg Return Value - mresReply

mresReply ([MRESULT](#)) - returns
Message-return data.

WinSendDlgItemMsg - Parameters

hwndDlg ([HWND](#)) - input
Parent-window handle.

idItem ([ULONG](#)) - input
Identity of the child window.

It must be greater or equal to 0 and less or equal to 0xFFFF.

msg ([ULONG](#)) - input
Message identity.

mp1 ([MPARAM](#)) - input
Message parameter 1.

mp2 ([MPARAM](#)) - input
Message parameter 2.

mresReply ([MRESULT](#)) - returns
Message-return data.

WinSendDlgItemMsg - Remarks

This function is equivalent to the [WinSendMessage](#) function, in which the receiving window procedure is specified by means of the item identity of the child window and parent-window handle.

It does not return until the message has been processed by the dialog item, whose return value is returned in *mresReply*.

The call is equivalent to:

```
WinSendMessage (WinWindowFromID(hwndDlg, idItem), msgid, param1, param2, reply);
```

This function is valid for any window with children; however, it is typically used for dialog items in a dialog window.

WinSendDlgItemMsg - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinSendDlgItemMsg - Example Code

This example processes an application-defined message (IDM_SHOW) and sets a check mark next to the selected item.

```
#define INCL_WIN
#define INCL_WINDIALOGS
#include <OS2.H>
```

```

#define IDM_SHOW 902

HWND hwndFrame;
ULONG msg;
MPARAM mp1;

/* Inside client procedure. */

switch(msg)
{
case WM_COMMAND:
/* The user has chosen a menu item. Process the selection */
/* accordingly. */

switch ( SHORT1FROMMP( mp1 ) )
{

case IDM_SHOW:
WinSendDlgItemMsg(hwndFrame, (ULONG) FID_MENU,
(ULONG) MM_SETITEMATTR,
MPFROM2SHORT(IDM_SHOW, TRUE),
MPFROM2SHORT(MIA_CHECKED,MIA_CHECKED));

break;

}
break;
}

```

WinSendMsg

WinSendMsg - Syntax

This function sends a message with identity *ulMsgid* to *hwnd*, passing *mpParam1* and *mpParam2* as the parameters to the window.

```

#define INCL_WINMESSAGEGR /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HWND      hwnd;          /* Window handle. */
ULONG     ulMsgid;       /* Message identity. */
MPARAM    mpParam1;      /* Parameter 1. */
MPARAM    mpParam2;      /* Parameter 2. */
MRESULT   mresReply;     /* Message-return data. */

```

```
mresReply = WinSendMsg(hwnd, ulMsgid, mpParam1,  
                        mpParam2);
```

WinSendMsg Parameter - hwnd

hwnd (**HWND**) - input
Window handle.

WinSendMsg Parameter - ulMsgid

ulMsgid (**ULONG**) - input
Message identity.

WinSendMsg Parameter - mpParam1

mpParam1 (**MPARAM**) - input
Parameter 1.

WinSendMsg Parameter - mpParam2

mpParam2 (**MPARAM**) - input
Parameter 2.

WinSendMsg Return Value - mresReply

mresReply (**MRESULT**) - returns
Message-return data.

WinSendMsg - Parameters

hwnd ([HWND](#)) - input
Window handle.

ulMsgid ([ULONG](#)) - input
Message identity.

mpParam1 ([MPARAM](#)) - input
Parameter 1.

mpParam2 ([MPARAM](#)) - input
Parameter 2.

mresReply ([MRESULT](#)) - returns
Message-return data.

WinSendMessage - Remarks

mresReply is the value returned by the window procedure that is invoked. For standard window classes, the values of *mresReply* are documented with the message definitions.

This function does not complete until the message has been processed by the window procedure whose return value is returned in *mresReply*.

If the window receiving the message belongs to the same thread, the window function is called immediately as a subroutine. If the window is of another thread or process, the operating system switches to the appropriate thread that enters the necessary window procedure recursively. The message is not placed in the queue of the destination thread.

If a message is sent from one process to another and the message contains a pointer, the receiving process may not have read/write access to the memory referenced by the pointer. If the receiving process is expected to update that memory, this must be done using shared memory. For more information about Dynamic Data Exchange (DDE) and shared memory, see "Dynamic Data Exchange" section of the *Presentation Manager Programming Guide - Advanced Topics*.

WinSendMessage - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

PMERR_WINDOW_NOT_LOCKED (0x1007)
The window specified in WinSendMessage was not locked.

WinSetAcceleratorTable

WinSetAcceleratorTable - Syntax

This function sets the window-accelerator, or queue-accelerator table.

```
#define INCL_WINACCELERATORS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
HACCEL    haccelAccel; /* Accelerator-table handle. */
HWND     hwndFrame;    /* Frame-window handle. */
BOOL      rc;          /* Success indicator. */

rc = WinSetAccelTable(hab, haccelAccel, hwndFrame);
```

WinSetAccelTable Parameter - hab

hab (**HAB**) - input
Anchor-block handle.

WinSetAccelTable Parameter - haccelAccel

haccelAccel (**HACCEL**) - input
Accelerator-table handle.

NULLHANDLE
Remove any accelerator table in effect for the window or the queue

Other
Accelerator-table handle.

WinSetAccelTable Parameter - hwndFrame

hwndFrame (**HWND**) - input
Frame-window handle.

NULLHANDLE
Set the queue-accelerator table

Other
Set the window-accelerator table.

WinSetAccelTable Return Value - rc

rc (**BOOL**) - returns

Success indicator.

TRUE

Successful completion

FALSE

Error occurred.

WinSetAccelTable - Parameters

hab ([HAB](#)) - input

Anchor-block handle.

haccelAccel ([HACCEL](#)) - input

Accelerator-table handle.

NULLHANDLE

Remove any accelerator table in effect for the window or the queue

Other

Accelerator-table handle.

hwndFrame ([HWND](#)) - input

Frame-window handle.

NULLHANDLE

Set the queue-accelerator table

Other

Set the window-accelerator table.

rc ([BOOL](#)) - returns

Success indicator.

TRUE

Successful completion

FALSE

Error occurred.

WinSetAccelTable - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)

An invalid window handle was specified.

PMERR_INVALID_HACCEL (0x101A)

An invalid accelerator-table handle was specified.

WinSetActiveWindow

WinSetActiveWindow - Syntax

This function makes the frame window the active window.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HWND    hwndDesktop; /* Desktop-window handle. */
HWND    hwnd;         /* Window handle. */
BOOL    rc;           /* Active-window-set indicator. */
```

```
rc = WinSetActiveWindow(hwndDeskTop, hwnd);
```

WinSetActiveWindow Parameter - hwndDeskTop

- hwndDeskTop (HWND)** - input
Desktop-window handle.
- HWND_DESKTOP The desktop-window handle
 - Other Specified desktop-window handle.

WinSetActiveWindow Parameter - hwnd

- hwnd (HWND)** - input
Window handle.
- hwnd* is either the frame window or its child. If it is a child, the parent frame window will become the active window.

WinSetActiveWindow Return Value - rc

- rc (BOOL)** - returns
Active-window-set indicator.
- TRUE Active window is set
 - FALSE Active window is not set.

WinSetActiveWindow - Parameters

- hwndDeskTop (HWND)** - input
Desktop-window handle.
- HWND_DESKTOP The desktop-window handle
 - Other Specified desktop-window handle.

- hwnd (HWND)** - input
Window handle.

hwnd is either the frame window or its child. If it is a child, the parent frame window will become the active window.

rc ([BOOL](#)) - returns
Active-window-set indicator.

TRUE

Active window is set

FALSE

Active window is not set.

WinSetActiveWindow - Remarks

This function is equivalent to the [WinFocusChange](#) function, in which the *flFocusChange* parameter is set.

WinSetActiveWindow - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinSetCapture

WinSetCapture - Syntax

This function captures all pointing device messages.

```
#define INCL_WININPUT /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwndDesktop; /* Desktop-window handle, or HWND_DESKTOP. */
HWND    hwnd;         /* Handle of the window that is to receive all pointing device messages. */
BOOL    rc;           /* Success indicator. */

rc = WinSetCapture(hwndDesktop, hwnd);
```

WinSetCapture Parameter - hwndDesktop

hwndDesktop ([HWND](#)) - input
Desktop-window handle, or HWND_DESKTOP.

WinSetCapture Parameter - hwnd

hwnd ([HWND](#)) - input
Handle of the window that is to receive all pointing device messages.

hwnd can take the special value HWND_THREADCAPTURE to capture the pointing device to the current thread rather than to a particular window. HWND_THREADCAPTURE is unique among window handles.

If *hwnd* is NULLHANDLE, pointing device capture is released.

WinSetCapture Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE

Successful completion.

FALSE

Error occurred. If the pointing device has already been captured by another thread or window, the call fails. This is to prevent applications from removing the capture from other windows or threads.

WinSetCapture - Parameters

hwnDDesktop ([HWND](#)) - input
Desktop-window handle, or HWND_DESKTOP.

hwnD ([HWND](#)) - input
Handle of the window that is to receive all pointing device messages.

hwnD can take the special value HWND_THREADCAPTURE to capture the pointing device to the current thread rather than to a particular window. HWND_THREADCAPTURE is unique among window handles.

If *hwnD* is NULLHANDLE, pointing device capture is released.

rc ([BOOL](#)) - returns
Success indicator.

TRUE

Successful completion.

FALSE

Error occurred. If the pointing device has already been captured by another thread or window, the call fails. This is to prevent applications from removing the capture from other windows or threads.

WinSetCapture - Remarks

This function assigns the pointing device capture to *hwnD*.

With the pointing device capture set to a window, all pointing device input is directed to that window, regardless of whether the pointing device pointer is over that window.

When this function (*hwnDDesktop*, NULLHANDLE) is called to release the pointing device capture, a [WM_MOUSEMOVE](#) message is posted regardless of whether the pointing device pointer has actually moved. This ensures that the window below the pointing device, at that time, is able to change features, such as the shape of the pointing device pointer.

If this function (*hwnDDesktop*, HWND_THREADCAPTURE) is called, the pointing device is captured to the current thread. Pointing device QMSGs processed in this manner have NULLHANDLE window handles, and the pointing device coordinates are relative to the screen.

This function returns an unlocked window handle.

It must only be called while processing pointing device or keyboard input. A message box or dialog box must not be created while the pointing device is captured.

WinSetCapture - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinSetCapture - Example Code

This example uses the WinSetCapture call to capture the mouse until the button is released. The user has selected a specific object with mouse button 2.

```
#define INCL_WININPUT
#include <OS2.H>
HWND hwnd;
USHORT msg;
WinSetCapture(hwnd,HWND_DESKTOP);
switch (msg) {
    case WM_BUTTON2DOWN:

        /******
        /* An object has been picked. Set the mouse capture until
        /* a 'button up' message is detected.
        /******
        if (hwnd != WinQueryFocus(HWND_DESKTOP)){
            WinSetFocus(HWND_DESKTOP, hwnd);
        }
        WinSetCapture(HWND_DESKTOP, hwnd);
        break;
    }
}
```

WinSetClassMsgInterest

WinSetClassMsgInterest - Syntax

This function sets the message interest of a window class.

```
#define INCL_WINMESSAGEGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;           /* Anchor-block handle. */
PSZ      pszClassName;  /* Window-class name. */
ULONG    ulMsgClass;    /* Message class to have interest level set. */
LONG     lControl;      /* Interest identifier for the message class. */
BOOL     rc;            /* Interest-changed indicator. */

rc = WinSetClassMsgInterest(hab, pszClassName,
                           ulMsgClass, lControl);
```

WinSetClassMsgInterest Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinSetClassMsgInterest Parameter - pszClassName

pszClassName ([PSZ](#)) - input
Window-class name.

WinSetClassMsgInterest Parameter - ulMsgClass

ulMsgClass ([ULONG](#)) - input
Message class to have interest level set.

msgid A single message identity (for example, [WM_SHOW](#)).

SMIM_ALL All messages (except for WM_QUIT if *lControl* is SMI_AUTODISPATCH or SMI_NOINTEREST).

WinSetClassMsgInterest Parameter - lControl

lControl ([LONG](#)) - input
Interest identifier for the message class.

SMI_INTEREST Interested in the message, or messages

SMI_NOINTEREST Not interested in the message, or messages

SMI_AUTODISPATCH Interested in the message or messages, but they are to be automatically dispatched to the window procedure.

WinSetClassMsgInterest Return Value - rc

rc ([BOOL](#)) - returns
Interest-changed indicator.

TRUE Interest successfully changed

FALSE Interest not successfully changed.

WinSetClassMsgInterest - Parameters

hAb ([HAB](#)) - input
Anchor-block handle.

pszClassName ([PSZ](#)) - input
Window-class name.

ulMsgClass ([ULONG](#)) - input
Message class to have interest level set.

msgid A single message identity (for example, [WM_SHOW](#)).

SMIM_ALL All messages (except for WM_QUIT if *lControl* is SMI_AUTODISPATCH or SMI_NOINTEREST).

IControl ([LONG](#)) - input

Interest identifier for the message class.

SMI_INTEREST

Interested in the message, or messages

SMI_NOINTEREST

Not interested in the message, or messages

SMI_AUTODISPATCH

Interested in the message or messages, but they are to be automatically dispatched to the window procedure.

rc ([BOOL](#)) - returns

Interest-changed indicator.

TRUE

Interest successfully changed

FALSE

Interest not successfully changed.

WinSetClassMsgInterest - Remarks

This function has no effect unless the [MsgControlHook](#) hook, which is invoked by this function, has been set. The interest for [WM_QUIT](#) cannot be set to SMI_AUTODISPATCH using SMIM_ALL, because [WM_QUIT](#) is the normal means of terminating an application. It can be set specifically, if required.

WinSetClassMsgInterest - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)

An invalid window handle was specified.

WinSetClassThunkProc

WinSetClassThunkProc - Syntax

This function associates a pointer-conversion procedure with a window class.

```
#define INCL_WINTHUNKAPI /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

PSZ      pszClassName; /* Window-class name. */
PFN      pfnThunkProc; /* Pointer-conversion procedure identifier. */
BOOL     rc;           /* Success indicator. */

rc = WinSetClassThunkProc(pszClassName, pfnThunkProc);
```

WinSetClassThunkProc Parameter - pszClassName

pszClassName ([PSZ](#)) - input
Window-class name.

WinSetClassThunkProc Parameter - pfnThunkProc

pfnThunkProc ([PFN](#)) - input
Pointer-conversion procedure identifier.

- | | |
|-------|--|
| NULL | Any existing pointer-conversion procedure is dissociated from this class.

By default, a class has no pointer-conversion procedure associated with it. |
| Other | The pointer-conversion procedure to be associated with this class. |
-

WinSetClassThunkProc Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	An error occurred.

WinSetClassThunkProc - Parameters

pszClassName ([PSZ](#)) - input
Window-class name.

pfnThunkProc ([PFN](#)) - input
Pointer-conversion procedure identifier.

NULL	Any existing pointer-conversion procedure is dissociated from this class. By default, a class has no pointer-conversion procedure associated with it.
Other	The pointer-conversion procedure to be associated with this class.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	An error occurred.

WinSetClassThunkProc - Remarks

This function does not alter the pointer-conversion procedure associated with any existing window. It changes the pointer-conversion procedure that will be associated with a window created with a subsequent [WinCreateWindow](#) or [WinCreateStdWindow](#) function.

WinSetClipbrdData

WinSetClipbrdData - Syntax

This call puts data into the clipboard.

```
#define INCL_WINCLIPBOARD /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>
```

```

HAB      hab;          /* Anchor-block handle. */
ULONG    ulh;          /* General handle to the data object being set into the clipboard. */
ULONG    ulfmt;        /* Clipboard format of the data object referenced by ulh. */
ULONG    flFmtInfo;    /* Information. */
BOOL      rc;          /* Data-placed indicator. */

rc = WinSetClipbrdData(hab, ulh, ulfmt, flFmtInfo);

```

WinSetClipbrdData Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinSetClipbrdData Parameter - ulh

ulh ([ULONG](#)) - input
General handle to the data object being set into the clipboard.

If NULLHANDLE, a [WM_RENDERFMT](#) message is sent to the clipboard-owner window to render the format when [WinQueryClipbrdData](#) is called with the specified format.

Once the data has been set into the clipboard, this handle can no longer be used by the application.

If CFI_POINTER is specified, this parameter contains a pointer to memory. The memory must have been allocated as unnamed and shareable, by DosAllocSharedMem with the OBJ_GIVEABLE attribute.

WinSetClipbrdData Parameter - ulfmt

ulfmt ([ULONG](#)) - input
Clipboard format of the data object referenced by *ulh*.

The standard clipboard formats are shown in the following list. In addition to these predefined formats, any format value registered through the standard system atom manager displays this format in preference to privately-formatted data.

CF_TEXT	Text format. Each line ends with a carriage-return/line-feed combination. Tab characters separate fields within a line. A NULL character signals the end of the data.
CF_DSPTEXT	Text display format associated with private format.
CF_BITMAP	Bit map.
CF_DSPBITMAP	Bit-map display format associated with private format.
CF_METAFILE	Metafile.
CF_DSPMETAFILE	Metafile display format associated with private format.
CF_PALETTE	Palette.

WinSetClipbrdData Parameter - flFmtInfo

flFmtInfo ([ULONG](#)) - input
Information.

Information about the type of data referenced by the *ul/h* parameter.

Memory Model

One and only one of CFI_POINTER and CFI_HANDLE must be specified, unless CFI_OWNERDISPLAY is also specified.

CFI_POINTER

The *ul/h* parameter is a flat pointer to the object.

When this memory model is specified, the system:

- saves the address (accessing it from the shell process), so that if the setting application terminates normally or abnormally, the data is still available.
- frees the memory from the setting process, so that the setting application may no longer use it.

CFI_POINTER must be specified if the *ul/h* parameter is CF_TEXT or CF_DSPTEXT.

CFI_HANDLE

The *ul/h* parameter is the handle to a metafile or bit map.

This must be specified if the *ul/h* parameter is CF_BITMAP, CF_DSPBITMAP, CF_METAFILE or CF_DSPMETAFILE.

Usage Flags

CFI_OWNERFREE

Handle is not freed by [WinEmptyClipbrd](#). The application must free the data if necessary.

CFI_OWNERDISPLAY

This flag indicates that the format is drawn by the clipboard owner in the clipboard viewer window by means of the [WM_PAINTCLIPBOARD](#) message. The *ul/h* parameter should be NULL.

The values may be combined with bit-wise OR. Any number of the usage flags may be specified, but only one of the memory models.

WinSetClipbrdData Return Value - rc

rc ([BOOL](#)) - returns
Data-placed indicator.

Indicates whether data is placed into clipboard by this call:

TRUE

Data placed into clipboard.

FALSE

Data is not placed into clipboard, either an error occurred, or *ul/h* is NULL.

WinSetClipbrdData - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

ulh ([ULONG](#)) - input
General handle to the data object being set into the clipboard.

If NULLHANDLE, a [WM_RENDERFMT](#) message is sent to the clipboard-owner window to render the format when [WinQueryClipbrdData](#) is called with the specified format.

Once the data has been set into the clipboard, this handle can no longer be used by the application.

If CFI_POINTER is specified, this parameter contains a pointer to memory. The memory must have been allocated as unnamed and shareable, by DosAllocSharedMem with the OBJ_GIVEABLE attribute.

ulfmt ([ULONG](#)) - input
Clipboard format of the data object referenced by *ulh*.

The standard clipboard formats are shown in the following list. In addition to these predefined formats, any format value registered through the standard system atom manager displays this format in preference to privately-formatted data.

CF_TEXT	Text format. Each line ends with a carriage-return/line-feed combination. Tab characters separate fields within a line. A NULL character signals the end of the data.
CF_DSPTEXT	Text display format associated with private format.
CF_BITMAP	Bit map.
CF_DSPBITMAP	Bit-map display format associated with private format.
CF_METAFILE	Metafile.
CF_DSPMETAFILE	Metafile display format associated with private format.
CF_PALETTE	Palette.

flFmtInfo ([ULONG](#)) - input
Information.

Information about the type of data referenced by the *ulh* parameter.

Memory Model

One and only one of CFI_POINTER and CFI_HANDLE must be specified, unless CFI_OWNERDISPLAY is also specified.

CFI_POINTER	The <i>ulh</i> parameter is a flat pointer to the object. When this memory model is specified, the system: <ul style="list-style-type: none">saves the address (accessing it from the shell process), so that if the setting application terminates normally or abnormally, the data is still available.frees the memory from the setting process, so that the setting application may no longer use it.
-------------	--

CFI_POINTER must be specified if the *ulfmt* parameter is CF_TEXT or CF_DSPTEXT.

CFI_HANDLE	The <i>ulh</i> parameter is the handle to a metafile or bit map.
------------	--

This must be specified if the *ulfmt* parameter is CF_BITMAP, CF_DSPBITMAP, CF_METAFILE or CF_DSPMETAFILE.

Usage Flags

CFI_OWNERFREE	Handle is not freed by WinEmptyClipbrd . The application must free the data if necessary.
CFI_OWNERDISPLAY	This flag indicates that the format is drawn by the clipboard owner in the clipboard viewer window by means of the WM_PAINTCLIPBOARD message. The <i>ulh</i> parameter should be NULL.

The values may be combined with bit-wise OR. Any number of the usage flags may be specified, but only one of the memory models.

rc ([BOOL](#)) - returns
Data-placed indicator.

Indicates whether data is placed into clipboard by this call:

TRUE	Data placed into clipboard.
FALSE	Data is not placed into clipboard, either an error occurred, or <i>///</i> is NULL.

WinSetClipbrdData - Remarks

Data of the specified format, already in the clipboard, is freed by this call.

An object passed to the clipboard becomes the property of the system, and is not deleted when the process that created it terminates.

WinSetClipbrdData - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_FLAG (0x1019)
An invalid bit was set for a parameter. Use constants defined by PM for options, and do not set any reserved bits.

PMERR_INVALID_INTEGER_ATOM (0x1016)
The specified atom is not a valid integer atom.

WinSetClipbrdOwner

WinSetClipbrdOwner - Syntax

This function sets the current clipboard-owner window.

```
#define INCL_WINCLIPBOARD /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB    hab;  /* Anchor-block handle. */
HWND   hwnd; /* Window handle of the new clipboard owner. */
BOOL   rc;   /* Success indicator. */
```

```
rc = WinSetClipbrdOwner(hab, hwnd);
```

WinSetClipbrdOwner Parameter - hab

hab (**HAB**) - input
Anchor-block handle.

WinSetClipbrdOwner Parameter - hwnd

hwnd (**HWND**) - input
Window handle of the new clipboard owner.

NULLHANDLE	Clipboard-owner window is released and no new clipboard-owner window is established.
Other	Window handle of the new clipboard owner.

WinSetClipbrdOwner Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinSetClipbrdOwner - Parameters

hab (**HAB**) - input
Anchor-block handle.

hwnd (**HWND**) - input
Window handle of the new clipboard owner.

NULLHANDLE	Clipboard-owner window is released and no new clipboard-owner window is established.
Other	Window handle of the new clipboard owner.

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinSetClipbrdOwner - Remarks

The clipboard owner window receives the following clipboard-related messages at appropriate times:

[WM_DESTROYCLIPBOARD](#)
[WM_HSCROLLCLIPBOARD](#)
[WM_PAINTCLIPBOARD](#)
[WM_RENDERALLFMTS](#)
[WM_RENDERFMT](#)
[WM_SIZECLIPBOARD](#)
[WM_VSCROLLCLIPBOARD](#).

WinSetClipbrdOwner - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
 An invalid window handle was specified.

WinSetClipbrdViewer

WinSetClipbrdViewer - Syntax

This function sets the current clipboard-viewer window to a specified window.

```

#define INCL_WINCLIPBOARD /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
HWND     hwndNewClipViewer; /* Window handle of the new clipboard viewer. */
BOOL     rc;           /* Success indicator. */

rc = WinSetClipbrdViewer(hab, hwndNewClipViewer);

```

WinSetClipbrdViewer Parameter - hab

hab (**HAB**) - input
Anchor-block handle.

WinSetClipbrdViewer Parameter - hwndNewClipViewer

hwndNewClipViewer (**HWND**) - input
Window handle of the new clipboard viewer.

NULLHANDLE	The clipboard-viewer window is released and no new clipboard-viewer window is established.
Other	Window handle of the new clipboard viewer.

WinSetClipbrdViewer Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Valid, new clipboard-viewer window established
FALSE	There is no new clipboard-viewer window established.

WinSetClipbrdViewer - Parameters

hab (**HAB**) - input
Anchor-block handle.

hwndNewClipViewer (**HWND**) - input
Window handle of the new clipboard viewer.

NULLHANDLE

The clipboard-viewer window is released and no new clipboard-viewer window is established.

Other

Window handle of the new clipboard viewer.

rc ([BOOL](#)) - returns
Success indicator.

TRUE

Valid, new clipboard-viewer window established

FALSE

There is no new clipboard-viewer window established.

WinSetClipbrdViewer - Remarks

The clipboard-viewer window receives the [WM_DRAWCLIPBOARD](#) message when the contents of the clipboard change. This allows the viewer window to display an up-to-date version of the clipboard contents.

The clipboard must be open before this function is invoked.

WinSetClipbrdViewer - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinSetControlColors

WinSetControlColors - Syntax

This function sets the colors to be used by a control window. See [Colors Used by PM Controls](#).

```
#define INCL_WINSYS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwnd; /* Window handle. */
LONG      clrType; /* Control color index. */
ULONG     fCtlColor; /* Control Color Flags. */
ULONG     cCtlColor; /* Number of items being passed in pCtlColor. */
```

```
PCTLCOLOR    pCtlColor; /* Array of control colors, each comprising an index and value pair. */
LONG         rc;         /* Number of control colors returned in pCtlColor. */

rc = WinSetControlColors(hwnd, clrType, fCtlColor,
                        cCtlColor, pCtlColor);
```

WinSetControlColors Parameter - hwnd

hwnd ([HWND](#)) - input
Window handle.

WinSetControlColors Parameter - clrType

clrType ([LONG](#)) - input
Control color index.

Must be one of the following control color indexes.

CCT_STATIC	Static bitmap.
CCT_STATICTEXT	Static text.
CCT_GROUPBOX	Group Box.
CCT_PUSHBUTTON	Push button.
CCT_CHECKBOX	Check box.
CCT_RADIOBUTTON	Radio button.
CCT_ENTRYFIELD	Entry field.
CCT_LISTBOX	List box.
CCT_COMBOBOX	Combo box.
CCT_SCROLLBAR	Scroll bar.
CCT_FRAME	Window frame.
CCT_MENU	Menu.
CCT_TITLEBAR	Title bar.
CCT_SPINBUTTON	Spin button.
CCT_SLIDER	Slider.
CCT_CIRCULARSLIDER	Circular slider.
CCT_VALUESET	Value set.
CCT_MLE	Multiple line entry field.
CCT_CONTAINER	Container.
CCT_NOTEBOOK	Notebook.

WinSetControlColors Parameter - fCtlColor

fCtlColor (**ULONG**) - input
Control Color Flags.

CCF_GLOBAL Set global default colors (default)

CCF_APPLICATION Set application default colors (used on current thread)

WinSetControlColors Parameter - cCtlColor

cCtlColor (**ULONG**) - input
Number of items being passed in *pCtlColor*.

WinSetControlColors Parameter - pCtlColor

pCtlColor (**PCTLCOLOR**) - in/out
Array of control colors, each comprising an index and value pair.

WinSetControlColors Return Value - rc

rc (**LONG**) - returns
Number of control colors returned in *pCtlColor*.

TRUE Successful completion.

FALSE Error occurred, invalid parameters.

WinSetControlColors - Parameters

hwnd (**HWND**) - input
Window handle.

clrType (**LONG**) - input
Control color index.

Must be one of the following control color indexes.

CCT_STATIC	Static bitmap.
CCT_STATICTEXT	Static text.
CCT_GROUPBOX	Group Box.
CCT_PUSHBUTTON	Push button.
CCT_CHECKBOX	Check box.
CCT_RADIOBUTTON	Radio button.
CCT_ENTRYFIELD	Entry field.
CCT_LISTBOX	List box.
CCT_COMBOBOX	Combo box.
CCT_SCROLLBAR	Scroll bar.
CCT_FRAME	Window frame.
CCT_MENU	Menu.
CCT_TITLEBAR	Title bar.
CCT_SPINBUTTON	Spin button.
CCT_SLIDER	Slider.
CCT_CIRCULARSLIDER	Circular slider.
CCT_VALUESET	Value set.
CCT_MLE	Multiple line entry field.
CCT_CONTAINER	Container.
CCT_NOTEBOOK	Notebook.

fCtlColor (**ULONG**) - input
Control Color Flags.

CCF_GLOBAL	Set global default colors (default)
CCF_APPLICATION	Set application default colors (used on current thread)

cCtlColor (**ULONG**) - input
Number of items being passed in *pCtlColor*.

pCtlColor (**PCTLCOLOR**) - in/out
Array of control colors, each comprising an index and value pair.

rc (**LONG**) - returns
Number of control colors returned in *pCtlColor*.

TRUE	Successful completion.
FALSE	Error occurred, invalid parameters.

WinSetControlColors - Remarks

This function sets one or more of the colors to be used by a control window of the type specified by *ColorType*. If *hwnd* is a valid control window handle, the colors are set as presentation parameters for that window. If *hwnd* is set to `HWND_DESKTOP`, the default colors being used by that type of control window are set.

To set the default control colors for the current thread, specify `CCF_APPLICATION`. Be sure to issue the call to `WinSetColors` from the same thread that created the control windows, otherwise the call to `WinSetControlColors` will have no effect. To set all the colors used by a control window at once, specify `CCF_GLOBAL`, which is the default.

Each item in the array should contain a valid index and value pair (`CTLCOLOR`). The control color index must be a valid `CCI_` constant. The control color value can be one of the following:

- A valid RGB color

Note: Valid RGB colors include `SYSCLR_` values, which are actually indexes but can be used by graphics functions in RGB mode.
- `CCV_DEFAULT`, which sets the color to its default value
- `CCV_IGNORE`, which leaves the color for this index unchanged.

If `CCV_DEFAULT` is used when *hwnd* is a valid control window, the presentation parameter that maps to the specified `CCI_` index is removed.

If an RGB value that is not a pure color is specified as one of the color values, and if that color is used to draw lines with the control, the end result is not defined. Although dithered colors are okay for filled areas such as backgrounds, they cannot be used for lines.

This function can only be used for setting the colors of standard PM controls.

WinSetControlColors - Related Functions

WinSetCp

WinSetCp - Syntax

This function sets the code page for a queue.

```

#define INCL_WINCOUNTRY /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

```

```
HMQ      hmq;          /* Message-queue handle. */
ULONG    ulCodePage;   /* Code page. */
BOOL      rc;          /* Success indicator. */

rc = WinSetCp(hmq, ulCodePage);
```

WinSetCp Parameter - hmq

hmq (**HMQ**) - input
Message-queue handle.

WinSetCp Parameter - ulCodePage

ulCodePage (**ULONG**) - input
Code page.

Either of the two ASCII code pages specified in CONFIG.SYS can be selected.

WinSetCp Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinSetCp - Parameters

hmq (**HMQ**) - input
Message-queue handle.

ulCodePage (**ULONG**) - input
Code page.

Either of the two ASCII code pages specified in CONFIG.SYS can be selected.

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
------	-----------------------

FALSE

Error occurred.

WinSetCp - Remarks

The following is the list of valid code pages:

Country	Code Page
Canadian-French	863
Desktop Publishing	1004
Iceland	861
Latin 1 Multilingual	850
Latin 2 Multilingual	852
Nordic	865
Portuguese	860
Turkey	857
U.S. (IBM PC)	437

Code page 1004 is compatible with Microsoft** Windows**.

The following EBCDIC code pages, based on character set 697, are also available for output:

Country	Code Page
Austrian/German	273
Belgian	500
Brazil	037
Czechoslovakia	870
Danish/Norwegian	277
Finnish/Swedish	278
French	297
Hungary	870
Iceland	871
International	500
Italian	280
Poland	870
Portuguese	037
Spanish	284
Turkey	1026
U.K.-English	285
U.S.-English	037
Yugoslavia	870

Code pages 274 (Belgian) and 282 (Portuguese) can be used to provide access to old data.

WinSetCp - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HMQ (0x1002)

An invalid message-queue handle was specified.

PMERR_RESOURCE_NOT_FOUND (0x100A)

The specified resource identity could not be found.

WinSetDesktopBkgnd

WinSetDesktopBkgnd - Syntax

This function sets the desktop window state.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwndDesktop; /* Desktop-window handle. */
PDESKTOP  pDesktopState; /* Desktop-state structure. */
HBITMAP    hbm; /* Desktop background bit-map handle loaded or set. */
```

```
hbm = WinSetDesktopBkgnd(hwndDesktop, pDesktopState);
```

WinSetDesktopBkgnd Parameter - hwndDesktop

hwndDesktop ([HWND](#)) - input
Desktop-window handle.

WinSetDesktopBkgnd Parameter - pDesktopState

pDesktopState ([PDESKTOP](#)) - input
Desktop-state structure.

If the flag is set, then the background is unaffected although the bit-map file may still be loaded and tiled, or scaled as requested.

WinSetDesktopBkgnd Return Value - hbm

hbm ([HBITMAP](#)) - returns
Desktop background bit-map handle loaded or set.

NULLHANDLE
Error occurred.

Other
Bit-map handle loaded, set, or both for desktop background. The bit-map handle returned may be different from that passed into call if any scaling or tiling is performed.

WinSetDesktopBkgnd - Parameters

hwndDesktop ([HWND](#)) - input
Desktop-window handle.

pDesktopState ([PDESKTOP](#)) - input
Desktop-state structure.

If the flag is set, then the background is unaffected although the bit-map file may still be loaded and tiled, or scaled as requested.

hbm ([HBITMAP](#)) - returns
Desktop background bit-map handle loaded or set.

NULLHANDLE
Error occurred.

Other

Bit-map handle loaded, set, or both for desktop background. The bit-map handle returned may be different from that passed into call if any scaling or tiling is performed.

WinSetDesktopBkgnd - Remarks

This function allows an application to present an image in the background of the desktop window. This application must be acting as the OS/2 PM shell in place of the IBM supplied shell. If the IBM supplied shell is executing it maintains control of the background of the desktop window, and WinSetDesktopBkgnd will have no effect on the desktop window background, but will indicate a successful return code. The background of the desktop window is that portion of the desktop on which no other windows have been painted.

The system assumes ownership of the bit map which forms the desktop background. This implies that once the bit map is set to form the desktop background, it is no longer available to an application and therefore must not be associated with any application presentation space or any symbol set LCID. The system repaints the desktop background automatically to show any changes.

The most recent invocation of this function sets the state of the desktop background. Consequently, any application which sets the desktop background must be aware that changing the desktop background every time the application is activated, which implies the repainting of the whole desktop, could be distracting, if not disorienting, to the user. Therefore, such an application should determine if the correct desktop background is already showing by processing the [WM_ACTIVATE](#) message and if its determining the desktop background state by using the [WinQueryDesktopBkgnd](#) function and checking the bit-map handle of the current desktop background with the desired bit-map handle.

When setting a new desktop background, it is important to ensure that any previous desktop background bit map is destroyed, in order to prevent the system becoming cluttered with unused bit maps.

WinSetDesktopBkgnd - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HPTR (0x101B)
An invalid pointer handle was specified.

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinSetDesktopBkgnd - Example Code

This example sets the desktop background with a bit map if it is not already set.

```
#define INCL_WINDESKTOP
#define INCL_WINWINDOWMGR
#include <OS2.H>
```

```
HWND    hwndDesktop;
```

```

HAB      hab;
DESKTOP DeskTopState;
HBITMAP hbm;
HBITMAP hbm_user;

WinQueryDesktopBkgnd(HWND_DESKTOP,
                    &DeskTopState);

if (hbm_user != DeskTopState.hbm)
{
    DeskTopState.fl = SDT_LOADFILE;
    /* the szFile is used to load the bit map because*/
    /* the fl parameter is set to SDT_LOADFILE.      */
    strcpy(DeskTopState.szFile, "fruit.bmp");
    DeskTopState.hbm = hbm_user;
    WinSetDesktopBkgnd(hwndDesktop,
                      &DeskTopState);
}

```

WinSetDlgItemShort

WinSetDlgItemShort - Syntax

This function converts an integer value into the text of a dialog item.

```

#define INCL_WINDIALOGS /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HWND      hwndDlg; /* Parent-window handle. */
ULONG     idItem;  /* Identity of the child window whose text is to be changed. */
USHORT    usValue; /* Integer value used to generate the dialog item text. */
BOOL      fSigned; /* Sign indicator. */
BOOL      rc;      /* Success indicator. */

rc = WinSetDlgItemShort(hwndDlg, idItem, usValue,
                        fSigned);

```

WinSetDlgItemShort Parameter - hwndDlg

hwndDlg (**HWND**) - input
Parent-window handle.

WinSetDlgItemShort Parameter - idItem

idItem (**ULONG**) - input
Identity of the child window whose text is to be changed.

It must be greater or equal to 0 and less or equal to 0xFFFF.

WinSetDlgItemShort Parameter - usValue

usValue (**USHORT**) - input
Integer value used to generate the dialog item text.

WinSetDlgItemShort Parameter - fSigned

fSigned (**BOOL**) - input
Sign indicator.

TRUE	Signed integer value
FALSE	Unsigned integer value.

WinSetDlgItemShort Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinSetDlgItemShort - Parameters

hwndDlg ([HWND](#)) - input
Parent-window handle.

idItem ([ULONG](#)) - input
Identity of the child window whose text is to be changed.

It must be greater or equal to 0 and less or equal to 0xFFFF.

usValue ([USHORT](#)) - input
Integer value used to generate the dialog item text.

fSigned ([BOOL](#)) - input
Sign indicator.

TRUE Signed integer value
FALSE Unsigned integer value.

rc ([BOOL](#)) - returns
Success indicator.

TRUE Successful completion
FALSE Error occurred.

WinSetDlgItemShort - Remarks

The text produced is an ASCII string.

This function is valid for any window with children; however, it is typically used for dialog items in a dialog window.

WinSetDlgItemShort - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinSetDlgItemShort - Example Code

This example gets the text from a Dialog Box entry field as an integer value.

```
#define INCL_WINDIALOGS
#define INCL_WINBUTTONS
#include <OS2.H>
#define ID_ENTRYFLD 900
#define EM_SETTEXTLIMIT 2
HAB hab;
HWND hwnd;
ULONG msg;

switch(msg)
{
    case WM_INITDLG:

/* set entry field text limit. */
    WinSendDlgItemMsg(hwnd,
        /* identifier of the entry field window, which is */
        /* a child of the the window defined by hwnd.      */
        (ULONG)ID_ENTRYFLD,
        (ULONG)EM_SETTEXTLIMIT, /* Limit length */
        /* MPFROM2SHORT macro is of the form (low 2 bytes, */
        /* high 2 bytes), the the number passed is simply 2. */
        MPFROM2SHORT(2,0),
        (MPARAM)0);

/* set entry field to 12. */
    WinSetDlgItemShort(hwnd, ID_ENTRYFLD, (SHORT)12,TRUE);
}
```

WinSetDlgItemText

WinSetDlgItemText - Syntax

This function sets a text string in a dialog item.

```
#define INCL_WINDIALOGS /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HWND     hwndDlg; /* Parent-window handle. */
ULONG     idItem; /* Identity of the child window whose text is to be set. */
PSZ       pszText; /* Source string. */
BOOL      rc;      /* Success indicator. */

rc = WinSetDlgItemText(hwndDlg, idItem, pszText);
```

WinSetDlgItemText Parameter - hwndDlg

hwndDlg (**HWND**) - input
Parent-window handle.

WinSetDlgItemText Parameter - idItem

idItem (**ULONG**) - input
Identity of the child window whose text is to be set.

It must be greater or equal to 0 and less or equal to 0xFFFF.

WinSetDlgItemText Parameter - pszText

pszText (**PSZ**) - input
Source string.

This is the text string that is to be set into the dialog item.

WinSetDlgItemText Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinSetDlgItemText - Parameters

hwndDlg ([HWND](#)) - input
Parent-window handle.

idItem ([ULONG](#)) - input
Identity of the child window whose text is to be set.

It must be greater or equal to 0 and less or equal to 0xFFFF.

pszText ([PSZ](#)) - input
Source string.

This is the text string that is to be set into the dialog item.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinSetDlgItemText - Remarks

This function is valid for any window with children. However, it is typically used for dialog items in a dialog window.

This function is equivalent to:

```
WinSetWindowText (WinWindowFromID (hwndDlg, idItem), pszText);
```

WinSetDlgItemText - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinSetFileIcon

WinSetFileIcon - Syntax

WinSetFileIcon sets the icon for the file specified by *pFileName* to the icon specified by *picon*.

```
#define INCL_WINPOINTERS
#include <os2.h>

PSZ      pFileName; /* Pointer to file name. */
PICONINFO picon;    /* A pointer to an ICONINFO structure containing an icon specification. */
```

```
BOOL rc; /* Success indicator. */  
rc = WinSetFileIcon(pFileName, picon);
```

WinSetFileIcon Parameter - pFileName

pFileName ([PSZ](#)) - input
Pointer to file name.

A pointer to a zero-terminated string which contains the name of the file whose icon will be set.

WinSetFileIcon Parameter - picon

picon ([PICONINFO](#)) - input
A pointer to an [ICONINFO](#) structure containing an icon specification.

WinSetFileIcon Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinSetFileIcon - Parameters

pFileName ([PSZ](#)) - input
Pointer to file name.

A pointer to a zero-terminated string which contains the name of the file whose icon will be set.

picon ([PICONINFO](#)) - input
A pointer to an [ICONINFO](#) structure containing an icon specification.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinSetFileIcon - Remarks

The specified icon is written to the file's .ICON extended attribute.

WinSetFocus

WinSetFocus - Syntax

This function sets the focus window.

```
#define INCL_WININPUT /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HWND     hwndDeskTop; /* Desktop-window handle. */
HWND     hwndNewFocus; /* Window handle to receive the focus. */
BOOL     rc;           /* Success indicator. */

rc = WinSetFocus(hwndDeskTop, hwndNewFocus);
```

WinSetFocus Parameter - hwndDesktop

hwndDesktop (HWND) - input
Desktop-window handle.

HWND_DESKTOP	The desktop-window handle
Other	Specified desktop-window handle.

WinSetFocus Parameter - hwndNewFocus

hwndNewFocus (HWND) - input
Window handle to receive the focus.

If *hwndNewFocus* identifies a desktop window, no window on the device associated with the *hwndDesktop* receives the focus.

WinSetFocus Return Value - rc

rc (BOOL) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinSetFocus - Parameters

hwndDesktop (HWND) - input
Desktop-window handle.

HWND_DESKTOP	The desktop-window handle
Other	Specified desktop-window handle.

hwndNewFocus (HWND) - input
Window handle to receive the focus.

If *hwndNewFocus* identifies a desktop window, no window on the device associated with the *hwndDesktop* receives the focus.

rc (BOOL) - returns
Success indicator.

TRUE	Successful completion
------	-----------------------

FALSE

Error occurred.

WinSetFocus - Remarks

This function is equivalent to the [WinFocusChange](#) call in which the *flFocusChange* parameter is set to 0.

If no window has the input focus, [WM_CHAR](#) messages are posted to the queue of the active window and are not thrown away.

When this function is called a [WM_MOUSEMOVE](#) message is posted regardless of whether the pointing device pointer has actually moved. This ensures that the window below the pointing device, at that time, is able to change features, such as the shape of the pointing device pointer.

This function requires the existence of a message queue.

WinSetFocus - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

PMERR_CANNOT_SET_FOCUS (0x1037)
Focus cannot be set if a focus change is in progress, or if a system-modal window exists.

WinSetHook

WinSetHook - Syntax

This function installs an application procedure into a specified hook chain.

```
#define INCL_WINHOOKS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
HMQ      hmq;          /* Queue identity. */
LONG     lHookType;    /* Hook-chain type. */
PFN      pHookProc;    /* Address of the application hook procedure. */
HMODULE  Module;       /* Resource identity. */
BOOL     rc;           /* Success indicator. */

rc = WinSetHook(hab, hmq, lHookType, pHookProc,
    Module);
```

WinSetHook Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinSetHook Parameter - hmq

hmq ([HMQ](#)) - input
Queue identity.

This parameter identifies the queue to which the hook chain belongs. If *hmq* is set to NULLHANDLE, the hook is installed in the system hook chain. If *hmq* is set to HMQ_CURRENT, the hook is installed in the message queue associated with the current thread (calling thread).

WinSetHook Parameter - IHookType

IHookType ([LONG](#)) - input
Hook-chain type.

HK_SENDMSG

See [SendMsgHook](#)

HK_WINDOWDC

See [WindowDCHook](#)

WinSetHook Parameter - pHookProc

pHookProc ([PFN](#)) - input

Address of the application hook procedure.

WinSetHook Parameter - Module

Module ([HMODULE](#)) - input

Resource identity.

Handle of the module that contains the application hook procedure, as returned by the `DosLoadModule` or `DosQueryModuleHandle` call. This parameter can be `NULLHANDLE` when a queue hook is being installed by an application into its own message queue.

When hooking a system hook this parameter must be a valid module handle.

WinSetHook Return Value - rc

rc ([BOOL](#)) - returns

Success indicator.

TRUE

Successful completion

FALSE

An error occurred.

WinSetHook - Parameters

hab ([HAB](#)) - input

Anchor-block handle.

hmq ([HMQ](#)) - input

Queue identity.

This parameter identifies the queue to which the hook chain belongs. If *hmq* is set to `NULLHANDLE`, the hook is installed in the system hook chain. If *hmq* is set to `HMQ_CURRENT`, the hook is installed in the message queue associated with the current thread (calling thread).

IHookType ([LONG](#)) - input

Hook-chain type.

pHookProc ([PFN](#)) - input
 Address of the application hook procedure.

Module ([HMODULE](#)) - input
 Resource identity.

Handle of the module that contains the application hook procedure, as returned by the `DosLoadModule` or `DosQueryModuleHandle` call. This parameter can be `NULLHANDLE` when a queue hook is being installed by an application into its own message queue.

When hooking a system hook this parameter must be a valid module handle.

rc ([BOOL](#)) - returns
 Success indicator.

TRUE Successful completion
 FALSE An error occurred.

WinSetHook - Remarks

Queue hooks are called before system hooks.

This function installs the hook at the *head* of either the system or queue chain. The most recently installed hook is called first.

Use the [WinQueryWindowULong](#) function to obtain the queue handle associated with a window handle.

WinSetHook - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HMQ (0x1002)

An invalid message-queue handle was specified.

PMERR_PARAMETER_OUT_OF_RANGE (0x1003)

The value of a parameter was not within the defined valid range for that parameter.

WinSetKeyboardStateTable

WinSetKeyboardStateTable - Syntax

This function gets or sets the keyboard state.

```
#define INCL_WININPUT /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND     hwndDesktop; /* Desktop-window handle. */
PBYTE    abKeyStateTable; /* Key state table. */
BOOL     fSet; /* Set indicator. */
BOOL     rc; /* Success indicator. */

rc = WinSetKeyboardStateTable(hwndDesktop,
    abKeyStateTable, fSet);
```

WinSetKeyboardStateTable Parameter - hwndDesktop

hwndDesktop (**HWND**) - input
Desktop-window handle.

HWND_DESKTOP	The desktop-window handle
Other	Specified desktop-window handle.

WinSetKeyboardStateTable Parameter - abKeyStateTable

abKeyStateTable (**PBYTE**) - in/out
Key state table.

This is a 256-byte table indexed by virtual key value.

For any virtual key, the 0x80 bit is set if the key is down, and zero if it is up. The 0x01 bit is set if the key is toggled, (pressed an odd number of times), otherwise it is zero.

WinSetKeyboardStateTable Parameter - fSet

fSet (**BOOL**) - input
Set indicator.

TRUE	The keyboard state is set from <i>abKeyStateTable</i>
FALSE	The keyboard state is copied to <i>abKeyStateTable</i> .

WinSetKeyboardStateTable Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinSetKeyboardStateTable - Parameters

hwndDesktop (**HWND**) - input
Desktop-window handle.

HWND_DESKTOP	The desktop-window handle
Other	Specified desktop-window handle.

abKeyStateTable (**PBYTE**) - in/out
Key state table.

This is a 256-byte table indexed by virtual key value.

For any virtual key, the 0x80 bit is set if the key is down, and zero if it is up. The 0x01 bit is set if the key is toggled, (pressed an odd number of times), otherwise it is zero.

fSet (**BOOL**) - input
Set indicator.

TRUE	The keyboard state is set from <i>abKeyStateTable</i>
FALSE	The keyboard state is copied to <i>abKeyStateTable</i> .

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinSetKeyboardStateTable - Remarks

This function does not change the physical state of the keyboard, but changes the value returned by [WinGetKeyState](#), not [WinGetPhysKeyState](#).

To set the state of a single key, first get the entire table, modify the individual key, and then set the table from the modified value.

WinSetKeyboardStateTable - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinSetLboxItemText

WinSetLboxItemText - Syntax

This macro sets the text of the list box indexed item to buffer.

```

#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwndLbox; /* List box handle. */
LONG    index;    /* Index of the list box item. */
PSZ     psz;      /* Pointer to a null terminated string. */
BOOL    rc;       /* Success indicator. */

rc = WinSetLboxItemText(hwndLbox, index, psz);

```

WinSetLboxItemText Parameter - hwndLbox

hwndLbox ([HWND](#)) - input
List box handle.

WinSetLboxItemText Parameter - index

index (**LONG**) - input
Index of the list box item.

WinSetLboxItemText Parameter - psz

psz (**PSZ**) - input
Pointer to a null terminated string.

WinSetLboxItemText Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinSetLboxItemText - Parameters

hwndLbox (**HWND**) - input
List box handle.

index (**LONG**) - input
Index of the list box item.

psz (**PSZ**) - input
Pointer to a null terminated string.

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinSetLboxItemText - Remarks

This macro is defined as:

```
#define WinSetLboxItemText(hwndLbox, index, psz) \
    ((BOOL)WinSendMsg(hwndLbox, \
        LM_SETITEMTEXT, \
        MPFROMLONG(index), \
        MPFROMP(psz)))
```

This macro requires the existence of a message queue.

WinSetLboxItemText - Example Code

This example uses the WinSetLboxItemText call to set the months in a calendar list box.

```
#define INCL_WINDIALOGS
#include <OS2.H>

HWND    hwndLbox;
LONG    i;
typedef char MONTH[12];
MONTH months[12] = {"January", "February", "March",
    "April", "May", "June", "July",
    "August", "September", "October",
    "November", "December" };

for (i=0; i<12; i++)
{
    WinSetLboxItemText(hwndLbox,
        i,
        months[i]);
} /* endfor */
```

WinSetMenuItemText

WinSetMenuItemText - Syntax

This macro sets the text for Menu indexed item to buffer.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwndMenu; /* Menu window handle. */
USHORT     usId;     /* Identity of the menu item. */
PSZ        pText;    /* Text for the menu item. */
BOOL       rc;        /* Success indicator. */

rc = WinSetMenuItemText(hwndMenu, usId, pText);
```

WinSetMenuItemText Parameter - hwndMenu

hwndMenu ([HWND](#)) - input
Menu window handle.

WinSetMenuItemText Parameter - usId

usId ([USHORT](#)) - input
Identity of the menu item.

WinSetMenuItemText Parameter - pText

pText ([PSZ](#)) - input
Text for the menu item.

WinSetMenuItemText Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinSetMenuItemText - Parameters

hwndMenu ([HWND](#)) - input
Menu window handle.

usId ([USHORT](#)) - input
Identity of the menu item.

pText ([PSZ](#)) - input
Text for the menu item.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinSetMenuItemText - Remarks

This macro expands to:

```
#define WinSetMenuItemText (hwndMenu, usId, pszText)
( (BOOL)WinSendMsg(hwndMenu,
    MM_SETITEMTEXT,
    MPFROMSHORT(id),
    MPFROMP(pszText)) )
```

This function requires the existence of a message queue.

WinSetMsgInterest

WinSetMsgInterest - Syntax

This function sets a window's message interest.

```
#define INCL_WINMESSAGEGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND     hwnd;          /* Window handle. */
ULONG    ulMsgClass;    /* Message class to have interest level set. */
LONG     lControl;      /* Interest-identifier for the message class. */
BOOL     rc;            /* Interest-changed indicator. */

rc = WinSetMsgInterest(hwnd, ulMsgClass, lControl);
```

WinSetMsgInterest Parameter - hwnd

hwnd (**HWND**) - input
Window handle.

WinSetMsgInterest Parameter - ulMsgClass

ulMsgClass (**ULONG**) - input
Message class to have interest level set.

msgid	A single message identity (for example, WM_SHOW)
SMIM_ALL	All messages (except for WM_QUIT if <i>lControl</i> is SMI_AUTODISPATCH or SMI_NOINTEREST).

WinSetMsgInterest Parameter - lControl

lControl (**LONG**) - input
Interest-identifier for the message class.

SMI_RESET	Revert to interest specified for the window class.
SMI_INTEREST	Interested in the messages.
SMI_NOINTEREST	Not interested in the messages.
SMI_AUTODISPATCH	Interested in the message or messages, but they are to be automatically dispatched to the window procedure.

WinSetMsgInterest Return Value - rc

rc ([BOOL](#)) - returns
Interest-changed indicator.

TRUE	Interest successfully changed
FALSE	Interest not successfully changed.

WinSetMsgInterest - Parameters

hwnd ([HWND](#)) - input
Window handle.

ulMsgClass ([ULONG](#)) - input
Message class to have interest level set.

msgid	A single message identity (for example, WM_SHOW)
SMIM_ALL	All messages (except for WM_QUIT if <i>lControl</i> is SMI_AUTODISPATCH or SMI_NOINTEREST).

lControl ([LONG](#)) - input
Interest-identifier for the message class.

SMI_RESET	Revert to interest specified for the window class.
SMI_INTEREST	Interested in the messages.
SMI_NOINTEREST	Not interested in the messages.
SMI_AUTODISPATCH	Interested in the message or messages, but they are to be automatically dispatched to the window procedure.

rc ([BOOL](#)) - returns
Interest-changed indicator.

TRUE	Interest successfully changed
FALSE	Interest not successfully changed.

WinSetMsgInterest - Remarks

This function has no effect unless the [MsgControlHook](#) hook, which is invoked by this function, has been set. The interest for WM_QUIT cannot be set to SMI_AUTODISPATCH using SMIM_ALL, because WM_QUIT is the normal means of terminating an application. It can be set specifically, if required.

WinSetMsgInterest - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinSetMsgInterest - Example Code

This example uses the WinSetMsgInterest call to set the message interest of a window to only WM_SHOW messages.

```
#define INCL_WINMESSAGEGR
#define INCL_WINHOOKS
#include <OS2.H>

HWND hwnd;
HAB hab;
BOOL fSuccess;
/* Hook Procedure Prototype */

BOOL MsgCtlHook(HAB hab, LONG idContext, /* this hook can */
                HWND hwnd, PSZ pszClassname, /* be given any */
                ULONG ulMsgclass, /* name. */
                LONG idControl, PBOOL fSuccess);

main()
{
/* This function passes the hook procedure address to the system. */

WinSetHook(hab,
            (HMQ)0,
            MCHK_CLASSMSGINTEREST,
            (PFN)MsgCtlHook,
            (HMODULE)0); /* hook is into application queue. */

/* This function sets the message interest of a window class. */
WinSetMsgInterest(hwnd,
```

```

        WM_SHOW,
        SMI_AUTODISPATCH); /* interested in the */
        /* messages, but they are to */
        /* be automatically dispatched */
        /* to the window procedure. */
    }

    BOOL MsgCtlHook(HAB hab, LONG idContext,          /* this hook can */
                    HWND hwnd, PSZ pszClassname,      /* be given any */
                    ULONG ulMsgclass,                 /* name. */
                    LONG idControl, PBOOL fSuccess)
{

WinSetMsgMode

WinSetMsgMode - Syntax

This function indicates the mode for the generation and processing of messages for the private window class of an application.

```

#define INCL_WINMESSAGEGR /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HAB      hab;          /* Anchor block handle. */
PSZ      pszClassName; /* Window class name. */
LONG     lControl;     /* Message mode identifier. */
BOOL     rc;           /* Message delay indicator. */

rc = WinSetMsgMode(hab, pszClassName, lControl);

```

WinSetMsgMode Parameter - hab

hab (**HAB**) - input
Anchor block handle.

WinSetMsgMode Parameter - pszClassName

pszClassName (**PSZ**) - input
Window class name.

WinSetMsgMode Parameter - IControl

IControl (**LONG**) - input
Message mode identifier.

SMD_DELAYED The generation of messages may be delayed

SMD_IMMEDIATE The generation of messages will not be delayed.

WinSetMsgMode Return Value - rc

rc (**BOOL**) - returns
Message delay indicator.

TRUE Message mode successfully set

FALSE Message mode not successfully set.

WinSetMsgMode - Parameters

hab (**HAB**) - input
Anchor block handle.

pszClassName (**PSZ**) - input
Window class name.

IControl (**LONG**) - input
Message mode identifier.

SMD_DELAYED The generation of messages may be delayed

SMD_IMMEDIATE The generation of messages will not be delayed.

rc ([BOOL](#)) - returns
Message delay indicator.

TRUE	Message mode successfully set
FALSE	Message mode not successfully set.

WinSetMsgMode - Remarks

This function has no effect unless the [MsgControlHook](#) hook, which is invoked by this function, has been set.

WinSetMsgMode - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinSetMultWindowPos

WinSetMultWindowPos - Syntax

This function performs the [WinSetWindowPos](#) function for *cswp* windows, using *pswp*, an array of structures whose elements correspond to the input parameters of [WinSetWindowPos](#).

```

#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab; /* Anchor-block handle. */
PSWP     pswp; /* An array of set window position (SWP) structures. */
ULONG    cswp; /* Window count. */
BOOL     rc; /* Positioning success indicator. */

rc = WinSetMultWindowPos(hab, pswp, cswp);

```

WinSetMultWindowPos Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinSetMultWindowPos Parameter - pswp

pswp ([PSWP](#)) - input
An array of set window position ([SWP](#)) structures.

The elements of each correspond to the input parameters of [WinSetWindowPos](#).

WinSetMultWindowPos Parameter - cswp

cswp ([ULONG](#)) - input
Window count.

This parameter can be set to 0, representing an empty list of [SWP](#) structures.

WinSetMultWindowPos Return Value - rc

rc ([BOOL](#)) - returns
Positioning success indicator.

TRUE	Positioning succeeded
FALSE	Positioning failed.

WinSetMultWindowPos - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

pswp ([PSWP](#)) - input
An array of set window position ([SWP](#)) structures.

The elements of each correspond to the input parameters of [WinSetWindowPos](#).

cswp ([ULONG](#)) - input
Window count.

This parameter can be set to 0, representing an empty list of [SWP](#) structures.

rc ([BOOL](#)) - returns
Positioning success indicator.

TRUE	Positioning succeeded
FALSE	Positioning failed.

WinSetMultWindowPos - Remarks

All windows being positioned must have the same parent.

It is more efficient to use this function than to issue multiple [WinSetWindowPos](#) functions, as it causes less screen updating. If specifies a frame window, this function recalculates the sizes and positions of the frame controls. If the new window rectangle for any frame control is to be empty, instead of resizing or repositioning that control, it is hidden by (SWP_HIDE) instead. This eliminates needless processing of windows that are not visible. The window rectangle of the control in question is left in its original state. For example, if [WinSetWindowPos](#) is issued to change the size of a standard frame window to an empty rectangle, and [WinQueryWindowRect](#) is issued against the client window, the rectangle returned is not an empty rectangle, but the original client rectangle before [WinSetWindowPos](#) was issued.

WinSetMultWindowPos - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

PMERR_INVALID_FLAG (0x1019)
An invalid bit was set for a parameter. Use constants defined by PM for options, and do not set any reserved bits.

WinSetMultWindowPos - Example Code

This example uses the WinSetMultWindowPos to cascade up to 16 main windows.

```
#define INCL_WINWINDOWMGR
#include <OS2.H>

HWND ahwnd[16]; /* Array of window handles */
SWP aSwp[16]; /* Array of SWP structures */
SWP swp;
HAB hab;
LONG xcoord, ycoord;
LONG i=1;

/* Get the recommended window position */
WinQueryTaskSizePos(hab,
                    0,
                    &swp);

xcoord = swp.x;
ycoord = swp.y;

/* Initialize the array of SWP structures */
/* where each is displaced by (10,10) */
for (i=0; i<16 ; i++ )
{
    aSwp[i] = swp;
    aSwp[i].x = xcoord;
    aSwp[i].y = ycoord;
    xcoord += 10;
    ycoord += 10;
} /* endfor */

/* Get a list of all the main windows into the ahwnd array */
i=0
henum = WinBeginEnumWindows(HWND_DESKTOP);
do
{
    ahwnd[i] = WinGetNextWindow(henum);
}
while((ahwnd[i++]!= NULL) && i < 16);
WinEndEnumWindows(henum);
WinSetMultWindowPos(hab,aSwp,i-1);

WinSetObjectData

WinSetObjectData - Syntax

The WinSetObjectData function is called to set data on a workplace object.

```
#define INCL_WINWORKPLACE
#include <os2.h>

HOBJECT    object;        /* Handle to a workplace object. */
PSZ        pSetupString;  /* Pointer to object-specific parameters. */
BOOL       rc;            /* Success indicator. */

rc = WinSetObjectData(object, pSetupString);
```

WinSetObjectData Parameter - object

object ([HOBJECT](#)) - input
Handle to a workplace object.

WinSetObjectData Parameter - pSetupString

pSetupString ([PSZ](#)) - input
Pointer to object-specific parameters.

A pointer to a zero-terminated string which contains the object-specific parameters to the new object.

The *pSetupString* string is extracted when the wpSetup method is called. For a listing of setup strings, see individual object classes; See WPLaunchPad class definition for a discussion of setup string values used in Toolbar customization.

WinSetObjectData Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE
Successful completion.

FALSE

Error occurred.

WinSetObjectData - Parameters

object ([HOBJECT](#)) - input
Handle to a workplace object.

pSetupString ([PSZ](#)) - input
Pointer to object-specific parameters.

A pointer to a zero-terminated string which contains the object-specific parameters to the new object.

The *pSetupString* string is extracted when the wpSetup method is called. For a listing of setup strings, see individual object classes; See WPLaunchPad class definition for a discussion of setup string values used in Toolbar customization.

rc ([BOOL](#)) - returns
Success indicator.

TRUE
Successful completion.

FALSE
Error occurred.

WinSetObjectData - Remarks

The WinSetObjectData function will change settings on an object that was created with the WinCreateObject function.

Using [HOBJECT](#) for .INI files or files in which an application uses a rename/save/delete sequence is not supported.

WinSetOwner

WinSetOwner - Syntax

This function changes the owner window of a specified window.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwnd;           /* Window handle whose owner window is to be changed. */
HWND    hwndNewOwner;   /* Handle of the new owner. */
BOOL    rc;             /* Success indicator. */

rc = WinSetOwner(hwnd, hwndNewOwner);
```

WinSetOwner Parameter - hwnd

hwnd (**HWND**) - input
Window handle whose owner window is to be changed.

WinSetOwner Parameter - hwndNewOwner

hwndNewOwner (**HWND**) - input
Handle of the new owner.

NULLHANDLE	The window becomes "disowned"
Other	Handle of the new owner window.

WinSetOwner Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
------	-----------------------

FALSE

Error occurred.

WinSetOwner - Parameters

hwnd ([HWND](#)) - input

Window handle whose owner window is to be changed.

hwndNewOwner ([HWND](#)) - input

Handle of the new owner.

NULLHANDLE

The window becomes "disowned"

Other

Handle of the new owner window.

rc ([BOOL](#)) - returns

Success indicator.

TRUE

Successful completion

FALSE

Error occurred.

WinSetOwner - Remarks

The old owner window is not locked by this function.

The [WinQueryWindow](#) function can be used to get the handle of the owner window.

WinSetOwner - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)

An invalid window handle was specified.

WinSetParent

WinSetParent - Syntax

This function sets the parent for *hwnd* to *hwndNewParent*.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwnd;          /* Window handle. */
HWND    hwndNewParent; /* New parent window handle. */
BOOL    fRedraw;        /* Redraw indicator. */
BOOL    rc;             /* Parent-changed indicator. */

rc = WinSetParent(hwnd, hwndNewParent, fRedraw);
```

WinSetParent Parameter - hwnd

hwnd ([HWND](#)) - input
Window handle.

WinSetParent Parameter - hwndNewParent

hwndNewParent ([HWND](#)) - input
New parent window handle.

- This cannot be a descendant of *hwnd*.
- If this parameter is a desktop window handle or `HWND_DESKTOP`, *hwnd* becomes a main window.
- If this parameter is not equal to `HWND_OBJECT`, it must be a descendant of the same desktop window as *hwnd*.
- If this parameter is `HWND_OBJECT` or a window handle returned by [WinQueryObjectWindow](#), *hwnd* becomes an object window.

WinSetParent Parameter - fRedraw

fRedraw ([BOOL](#)) - input
Redraw indicator.

- TRUE**
If *hwnd* is visible, any necessary redrawing of both the old parent and the new parent windows is performed.
- FALSE**
No redrawing of the old and new parent windows is performed. This avoids an extra device update when subsequent calls cause the windows to be redrawn.

WinSetParent Return Value - rc

rc ([BOOL](#)) - returns
Parent-changed indicator.

- TRUE**
Parent successfully changed
- FALSE**
Parent not successfully changed.

WinSetParent - Parameters

hwnd ([HWND](#)) - input
Window handle.

hwndNewParent ([HWND](#)) - input
New parent window handle.

This cannot be a descendant of *hwnd*.

If this parameter is a desktop window handle or `HWND_DESKTOP`, *hwnd* becomes a main window.

If this parameter is not equal to `HWND_OBJECT`, it must be a descendant of the same desktop window as *hwnd*.

If this parameter is `HWND_OBJECT` or a window handle returned by [WinQueryObjectWindow](#), *hwnd* becomes an object window.

fRedraw ([BOOL](#)) - input
Redraw indicator.

TRUE
If *hwnd* is visible, any necessary redrawing of both the old parent and the new parent windows is performed.

FALSE
No redrawing of the old and new parent windows is performed. This avoids an extra device update when subsequent calls cause the windows to be redrawn.

rc ([BOOL](#)) - returns
Parent-changed indicator.

TRUE
Parent successfully changed

FALSE
Parent not successfully changed.

WinSetParent - Remarks

This function returns an error (`PMERR_INVALID_HWND`) if the user specifies the desktop window as the new parent of a window to which a clip region is currently set.

WinSetParent - Errors

Possible returns from [WinGetLastError](#)

`PMERR_INVALID_HWND` (0x1001)
An invalid window handle was specified.

`PMERR_INVALID_FLAG` (0x1019)
An invalid bit was set for a parameter. Use constants defined by PM for options, and do not set any reserved bits.

WinSetPointer

WinSetPointer - Syntax

This call sets the desktop-pointer handle.

```
#define INCL_WINPOINTERS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwndDesktop;    /* Desktop-window handle. */
HPOINTER  hptrNewPointer; /* New pointer handle. */
BOOL      rc;             /* Pointer-updated indicator. */

rc = WinSetPointer(hwndDesktop, hptrNewPointer);
```

WinSetPointer Parameter - hwndDesktop

hwndDesktop ([HWND](#)) - input
Desktop-window handle.

HWND_DESKTOP	The desktop-window handle
Other	Specified desktop-window handle.

WinSetPointer Parameter - hptrNewPointer

hptrNewPointer ([HPOINTER](#)) - input
New pointer handle.

NULL	Remove pointer from the screen.
Other	Pointer handle associated with <i>hwndDesktop</i> . Handles for application-defined pointers are returned by the WinLoadPointer and WinCreatePointer calls.

WinSetPointer Return Value - rc

rc ([BOOL](#)) - returns
Pointer-updated indicator.

TRUE	Pointer successfully updated
FALSE	Pointer not successfully updated.

WinSetPointer - Parameters

hwndDeskTop ([HWND](#)) - input
Desktop-window handle.

HWND_DESKTOP
The desktop-window handle
Other
Specified desktop-window handle.

hptrNewPointer ([HPOINTER](#)) - input
New pointer handle.

NULL
Remove pointer from the screen.
Other
Pointer handle associated with *hwndDeskTop*. Handles for application-defined pointers are returned by the [WinLoadPointer](#) and [WinCreatePointer](#) calls.

rc ([BOOL](#)) - returns
Pointer-updated indicator.

TRUE
Pointer successfully updated
FALSE
Pointer not successfully updated.

WinSetPointer - Remarks

This call is very efficient if *hptrNewPointer* is the same as the current pointer handle.

WinSetPointer - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

PMERR_INVALID_HPTR (0x101B)
An invalid pointer handle was specified.

PMERR_INV_CURSOR_BITMAP (0x205E)
An invalid pointer was referenced with WinSetPointer.

WinSetPointer - Example Code

This example calls WinLoadPointer to load an application-defined pointer. When processing the WM_MOUSEMOVE message, the loaded pointer is displayed by calling WinSetPointer.

```
#define INCL_WININPUT
#define INCL_WINPOINTERS
#include <OS2.H>
#define IDP_CROSSHAIR 900

HPOINTER hptrCrossHair;
USHORT msg;

switch(msg)
{
case WM_CREATE:
    hptrCrossHair = WinLoadPointer(HWND_DESKTOP,
                                  (ULONG)0, /* load from .exe file */
                                  IDP_CROSSHAIR); /* identifies the pointer */

case WM_MOUSEMOVE:
    WinSetPointer(HWND_DESKTOP, hptrCrossHair);
}
```

- [Glossary](#)

WinSetPointerOwner

WinSetPointerOwner - Syntax

This function is specific to OS/2 Version 2.1 or higher.

This function allows an application to declare that a pointer it created can now be used by ANY process in the system (not just the process that created the pointer).

```
#define INCL_WINPOINTERS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HPOINTER  hptr;      /* Handle of pointer. */
PID        pid;      /* Process identity. */
BOOL       fDestroy; /* Pointer destruction flag. */
BOOL       rc;        /* Success indicator. */

rc = WinSetPointerOwner(hptr, pid, fDestroy);
```

WinSetPointerOwner Parameter - hptr

hptr (**HPOINTER**) - input
Handle of pointer.

WinSetPointerOwner Parameter - pid

pid (**PID**) - input
Process identity.

WinSetPointerOwner Parameter - fDestroy

fDestroy (**BOOL**) - input
Pointer destruction flag.

TRUE	Pointer can be destroyed by the current owner.
FALSE	Pointer cannot be destroyed by any owner.

WinSetPointerOwner Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Pointer owner successfully updated.
FALSE	Pointer owner not successfully updated.

WinSetPointerOwner - Parameters

hptr ([HPOINTER](#)) - input
Handle of pointer.

pid ([PID](#)) - input
Process identity.

fDestroy ([BOOL](#)) - input
Pointer destruction flag.

TRUE	Pointer can be destroyed by the current owner.
FALSE	Pointer cannot be destroyed by any owner.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Pointer owner successfully updated.
FALSE	Pointer owner not successfully updated.

WinSetPointerOwner - Remarks

Setting *pid* to 0 actually makes the pointer global (available on all processes).

Setting *pid* to 0, or setting *fDestroy* to FALSE should be done with extreme care. The resources allocated with this pointer will never be freed by the system, unless the pointer is set back to an active process, and *fDestroy* is set to TRUE.

WinSetPointerOwner - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HPTR (0x101B)
An invalid pointer handle was specified.

WinSetPointerOwner - Related Functions

- [WinShowPointer](#)

WinSetPointerOwner - Example Code

This example makes a pointer global, allowing its use by other processes.

```
WinSetPointerOwner(hMyPtr, 0L, FALSE);
```

On Exit of a DLL/Application using global pointers, the following sample code frees the resources allocated by the system.

```
WinSetPointerOwner(hMyPtr, CurPid, TRUE);  
WinDestroyPointer(hMyPtr);
```

WinSetPointerPos

WinSetPointerPos - Syntax

This function sets the pointer position.

```

#define INCL_WINPOINTERS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND     hwndDesktop; /* Desktop-window handle. */
LONG     lx;          /* x-position of pointer in screen coordinates. */
LONG     ly;          /* y-position of pointer in screen coordinates. */
BOOL     rc;          /* Pointer position updated indicator. */

rc = WinSetPointerPos(hwndDesktop, lx, ly);

```

WinSetPointerPos Parameter - hwndDesktop

hwndDesktop (**HWND**) - input
Desktop-window handle.

HWND_DESKTOP	The desktop-window handle
Other	Specified desktop-window handle.

WinSetPointerPos Parameter - lx

lx (**LONG**) - input
x-position of pointer in screen coordinates.

WinSetPointerPos Parameter - ly

ly (**LONG**) - input
y-position of pointer in screen coordinates.

WinSetPointerPos Return Value - rc

rc (**BOOL**) - returns
Pointer position updated indicator.

TRUE	Pointer position successfully updated
FALSE	Pointer position not successfully updated.

WinSetPointerPos - Parameters

hwndDesktop ([HWND](#)) - input

Desktop-window handle.

HWND_DESKTOP

The desktop-window handle

Other

Specified desktop-window handle.

lx ([LONG](#)) - input

x-position of pointer in screen coordinates.

ly ([LONG](#)) - input

y-position of pointer in screen coordinates.

rc ([BOOL](#)) - returns

Pointer position updated indicator.

TRUE

Pointer position successfully updated

FALSE

Pointer position not successfully updated.

WinSetPointerPos - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)

An invalid window handle was specified.

WinSetPointerPos - Related Functions

WinSetPresParam

WinSetPresParam - Syntax

This function sets a presentation parameter for a window.

```
#define INCL_WINSYS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwnd;          /* Window handle. */
ULONG     idAttrType;     /* Type of presentation parameter attribute to be set. */
ULONG     cbAttrValueLen; /* Size of the buffer pointed to by the pAttrValue parameter. */
PVOID     pAttrValue;     /* Pointer to the presentation parameter's data. */
BOOL      rc;             /* Success indicator. */

rc = WinSetPresParam(hwnd, idAttrType, cbAttrValueLen,
                     pAttrValue);
```

WinSetPresParam Parameter - hwnd

hwnd (**HWND**) - input
Window handle.

This is the window to which changes of the presentation parameters are to be applied.

WinSetPresParam Parameter - idAttrType

idAttrType ([ULONG](#)) - input

Type of presentation parameter attribute to be set.

This parameter can be set to one of the following system-defined presentation parameter attribute types or an application-defined type.

PP_FOREGROUND_COLOR

Foreground color (in [RGB](#)) attribute.

PP_BACKGROUND_COLOR

Background color (in [RGB](#)) attribute.

PP_FOREGROUND_COLOR_INDEX

Foreground color index attribute.

PP_BACKGROUND_COLOR_INDEX

Background color index attribute.

PP_HILITE_FOREGROUND_COLOR

Highlighted foreground color (in [RGB](#)) attribute, for example for selected menu items.

PP_HILITE_BACKGROUND_COLOR

Highlighted background color (in [RGB](#)) attribute.

PP_HILITE_FOREGROUND_COLOR_INDEX

Highlighted foreground color index attribute.

PP_HILITE_BACKGROUND_COLOR_INDEX

Highlighted background color index attribute.

PP_DISABLED_FOREGROUND_COLOR

Disabled foreground color (in [RGB](#)) attribute.

PP_DISABLED_BACKGROUND_COLOR

Disabled background color (in [RGB](#)) attribute.

PP_DISABLED_FOREGROUND_COLOR_INDEX

Disabled foreground color index attribute.

PP_DISABLED_BACKGROUND_COLOR_INDEX

Disabled background color index attribute.

PP_BORDER_COLOR

Border color (in [RGB](#)) attribute.

PP_BORDER_COLOR_INDEX

Border color index attribute.

PP_FONT_NAME_SIZE

Font name and size attribute.

PP_ACTIVE_COLOR

Active color value of data type [RGB](#).

PP_ACTIVE_COLOR_INDEX

Active color index value of data type [LONG](#).

PP_INACTIVE_COLOR

Inactive color value of data type [RGB](#).

PP_INACTIVECOLORINDEX	Inactive color index value of data type LONG .
PP_ACTIVETEXTFGNDCOLOR	Active text foreground color value of data type RGB .
PP_ACTIVETEXTFGNDCOLORINDEX	Active text foreground color index value of data type LONG .
PP_ACTIVETEXTBGNDCOLOR	Active text background color value of data type RGB .
PP_ACTIVETEXTBGNDCOLORINDEX	Active text background color index value of data type LONG .
PP_INACTIVETEXTFGNDCOLOR	Inactive text foreground color value of data type RGB .
PP_INACTIVETEXTFGNDCOLORINDEX	Inactive text foreground color index value of data type LONG .
PP_INACTIVETEXTBGNDCOLOR	Inactive text background color value of data type RGB .
PP_INACTIVETEXTBGNDCOLORINDEX	Inactive text background color index value of data type LONG .
PP_SHADOW	Changes the color used for drop shadows on certain controls.
PP_USER	This is a user-defined presentation parameter.

WinSetPresParam Parameter - cbAttrValueLen

cbAttrValueLen ([ULONG](#)) - input
Size of the buffer pointed to by the *pAttrValue* parameter.

WinSetPresParam Parameter - pAttrValue

pAttrValue ([PVOID](#)) - input
Pointer to the presentation parameter's data.

WinSetPresParam Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	

Error occurred.

WinSetPresParam - Parameters

hwnd ([HWND](#)) - input
Window handle.

This is the window to which changes of the presentation parameters are to be applied.

idAttrType ([ULONG](#)) - input
Type of presentation parameter attribute to be set.

This parameter can be set to one of the following system-defined presentation parameter attribute types or an application-defined type.

PP_FOREGROUNDCOLOR
Foreground color (in [RGB](#)) attribute.

PP_BACKGROUNDCOLOR
Background color (in [RGB](#)) attribute.

PP_FOREGROUNDCOLORINDEX
Foreground color index attribute.

PP_BACKGROUNDCOLORINDEX
Background color index attribute.

PP_HILITEFOREGROUNDCOLOR
Highlighted foreground color (in [RGB](#)) attribute, for example for selected menu items.

PP_HILITEBACKGROUNDCOLOR
Highlighted background color (in [RGB](#)) attribute.

PP_HILITEFOREGROUNDCOLORINDEX
Highlighted foreground color index attribute.

PP_HILITEBACKGROUNDCOLORINDEX
Highlighted background color index attribute.

PP_DISABLEDFOREGROUNDCOLOR
Disabled foreground color (in [RGB](#)) attribute.

PP_DISABLEDBACKGROUNDCOLOR
Disabled background color (in [RGB](#)) attribute.

PP_DISABLEDFOREGROUNDCOLORINDEX
Disabled foreground color index attribute.

PP_DISABLEDBACKGROUNDCOLORINDEX
Disabled background color index attribute.

PP_BORDERCOLOR
Border color (in [RGB](#)) attribute.

PP_BORDERCOLORINDEX
Border color index attribute.

PP_FONTNAMESIZE
Font name and size attribute.

PP_ACTIVECOLOR
Active color value of data type [RGB](#).

PP_ACTIVECOLORINDEX
Active color index value of data type [LONG](#).

PP_INACTIVECOLOR	Inactive color value of data type RGB .
PP_INACTIVECOLORINDEX	Inactive color index value of data type LONG .
PP_ACTIVETEXTFGNDCOLOR	Active text foreground color value of data type RGB .
PP_ACTIVETEXTFGNDCOLORINDEX	Active text foreground color index value of data type LONG .
PP_ACTIVETEXTBGNDCOLOR	Active text background color value of data type RGB .
PP_ACTIVETEXTBGNDCOLORINDEX	Active text background color index value of data type LONG .
PP_INACTIVETEXTFGNDCOLOR	Inactive text foreground color value of data type RGB .
PP_INACTIVETEXTFGNDCOLORINDEX	Inactive text foreground color index value of data type LONG .
PP_INACTIVETEXTBGNDCOLOR	Inactive text background color value of data type RGB .
PP_INACTIVETEXTBGNDCOLORINDEX	Inactive text background color index value of data type LONG .
PP_SHADOW	Changes the color used for drop shadows on certain controls.
PP_USER	This is a user-defined presentation parameter.

cbAttrValueLen ([ULONG](#)) - input
Size of the buffer pointed to by the *pAttrValue* parameter.

pAttrValue ([PVOID](#)) - input
Pointer to the presentation parameter's data.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinSetPresParam - Remarks

This function associates the presentation parameter attribute identified by *idAttrType* with the window *hwnd*. If the attribute already exists for the window, its value is changed to the new value specified by *pAttrValue*. If the attribute does not exist, it is added to the window's presentation parameters, with the specified value. (See also [WinQueryPresParam](#) and [WinRemovePresParam](#)).

When a presentation parameter is set, a [WM_PRESPARAMCHANGED](#) message is sent to all windows owned by the window calling the WinSetPresParam function.

When switching from using color indexes to using RGB color values, you must call GpiCreateLogColorTable with the LCOLF_RGB parameter. Otherwise, this function will treat the RGB color passed as an index into a color table, rather than as an absolute color value.

WinSetPresParam - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinSetPresParam - Example Code

This example changes the border color to blue.

```
#define INCL_WINSYS
#define INCL_GPIBITMAPS /* for RGB2 structure definition. */
#include <OS2.H>

HWND hwnd;
RGB2 rgb2; /* Red, green, and blue color index. */
rgb2.bBlue = 200;
rgb2.bGreen = 10;
rgb2.bRed = 5;
rgb2.fcOptions = 0;

WinSetPresParam(hwnd,
                 PP_BORDERCOLOR,
                 (ULONG)sizeof(RGB2),
                 (PVOID)&rgb2);
```

This example changes the font to 18-point Courier. Note that the length parameter includes 10 characters for the font name and 1 for a null terminator.

```
#define INCL_WINSYS
#define INCL_GPIBITMAPS /* for RGB structure definition
#include <OS2.H>

HWND hwnd;

WinSetPresParam(hwnd,
                 PP_FONTNAME,
                 11,
                 (PVOID)"18.Courier");
```

WinSetRect

WinSetRect - Syntax

This function sets rectangle coordinates.

```
#define INCL_WINRECTANGLES /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
PRECTL   prclrect;     /* Rectangle to be updated. */
LONG     lLeft;        /* Left edge of rectangle. */
LONG     lBottom;      /* Bottom edge of rectangle. */
LONG     lRight;       /* Right edge of rectangle. */
LONG     lTop;         /* Top edge of rectangle. */
BOOL     rc;           /* Success indicator. */

rc = WinSetRect(hab, prclrect, lLeft, lBottom,
               lRight, lTop);
```

WinSetRect Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinSetRect Parameter - prclrect

prclrect ([PRECTL](#)) - in/out

Rectangle to be updated.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type **WRECT** may also be used, if supported by the language.

WinSetRect Parameter - ILeft

ILeft (**LONG**) - input
Left edge of rectangle.

WinSetRect Parameter - IBottom

IBottom (**LONG**) - input
Bottom edge of rectangle.

WinSetRect Parameter - IRight

IRight (**LONG**) - input
Right edge of rectangle.

WinSetRect Parameter - ITop

ITop (**LONG**) - input
Top edge of rectangle.

WinSetRect Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinSetRect - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

prclrect ([PRECTL](#)) - in/out
Rectangle to be updated.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) may also be used, if supported by the language.

lLeft ([LONG](#)) - input
Left edge of rectangle.

lBottom ([LONG](#)) - input
Bottom edge of rectangle.

lRight ([LONG](#)) - input
Right edge of rectangle.

lTop ([LONG](#)) - input
Top edge of rectangle.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinSetRect - Remarks

This function is equivalent to assigning the left, top, right, and bottom arguments to the appropriate fields of [RECTL](#).

WinSetRect - Example Code

This example calls WinQueryWindowRect to get the dimensions of the window, and then calls WinSetRect to downsize it.

```
#define INCL_WINRECTANGLES
#include <OS2.H>
HAB hab;
RECTL rcl;
HWND hwnd;

WinQueryWindowRect(hwnd, &rcl);          /* get window dimensions */
WinSetRect(hab,&rcl,
           rcl.xLeft - 10,
           rcl.yBottom -10,
           rcl.xRight - 10,
           rcl.yTop - 10);
```

WinSetRectEmpty

WinSetRectEmpty - Syntax

This function sets a rectangle empty.

```
#define INCL_WINRECTANGLES /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
PRECTL   prclrect;     /* Rectangle to be set empty. */
BOOL     rc;           /* Success indicator. */

rc = WinSetRectEmpty(hab, prclrect);
```

WinSetRectEmpty Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinSetRectEmpty Parameter - prclrect

prclrect ([PRECTL](#)) - in/out
Rectangle to be set empty.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) may also be used, if supported by the language.

WinSetRectEmpty Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinSetRectEmpty - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

prclrect ([PRECTL](#)) - in/out
Rectangle to be set empty.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) may also be used, if supported by the language.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinSetRectEmpty - Remarks

This function is equivalent to a [WinSetRect](#) (*hab*, *prclrect*, 0, 0, 0, 0) call.

WinSetSynchroMode

WinSetSynchroMode - Syntax

This function is intended for use in a distributed application.

```
#define INCL_WINMESSAGEGR /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HAB      hab;      /* Anchor-block handle. */
LONG     lMode;     /* Synchronization mode. */
BOOL     rc;        /* Success indicator. */

rc = WinSetSynchroMode(hab, lMode);
```

WinSetSynchroMode Parameter - hab

hab (**HAB**) - input
Anchor-block handle.

WinSetSynchroMode Parameter - lMode

lMode (**LONG**) - input
Synchronization mode.

SSM_SYNCHRONOUS	Synchronous mode
SSM_ASYNCHRONOUS	Asynchronous mode
SSM_MIXED	Mixed mode.

WinSetSynchroMode Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinSetSynchroMode - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

IMode ([LONG](#)) - input
Synchronization mode.

SSM_SYNCHRONOUS
Synchronous mode
SSM_ASYNCHRONOUS
Asynchronous mode
SSM_MIXED
Mixed mode.

rc ([BOOL](#)) - returns
Success indicator.

TRUE
Successful completion
FALSE
Error occurred.

WinSetSynchroMode - Remarks

This function allows an application whose message queue is distributed, to synchronize the processing of those messages. This is achieved by the use of the [MsgControlHook](#) hook which is invoked by this function.

WinSetSysColors

WinSetSysColors - Syntax

This function sets system color values.

```
#define INCL_WINSYS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND hwndDesktop; /* Desktop-window handle. */
ULONG flOptions; /* Options. */
ULONG ulFormat; /* Format of entries in the table, as follows. */
LONG lStart; /* Starting system color index. */
ULONG ulTablen; /* Number of elements. */
PLONG alTable; /* Table. */
BOOL rc; /* Success indicator. */

rc = WinSetSysColors(hwndDesktop, flOptions,
                    ulFormat, lStart, ulTablen, alTable);
```

WinSetSysColors Parameter - hwndDesktop

hwndDesktop ([HWND](#)) - input

Desktop-window handle.

HWND_DESKTOP

The desktop-window handle

Other

Specified desktop-window handle.

WinSetSysColors Parameter - flOptions

flOptions ([ULONG](#)) - input
Options.

LCOL_RESET

The system colors are all to be reset to default before processing the remainder of the data in this function.

LCOL_PURECOLOR

Color-dithering should not be used to create colors not available in the physical palette. If this option is set, only pure colors are used and no dithering is done.

WinSetSysColors Parameter - ulFormat

ulFormat ([ULONG](#)) - input
Format of entries in the table, as follows.

LCOLF_INDRGB

Array of (index,RGB) values. Each pair of entries is 8-bytes long, comprising 4 bytes for the index, and 4 bytes for the color value. For system color indexes, see *lStart*.

LCOLF_CONSECRGB

Array of (RGB) values, corresponding to color indexes *lStart* upwards. Each entry is 4-bytes long.

WinSetSysColors Parameter - lStart

lStart ([LONG](#)) - input
Starting system color index.

This parameter is applicable only if the *ulFormat* parameter is set to LCOLF_CONSECRGB.

The number of system colors (as defined below) is given by SYSCLR_CSYS_COLORS.

The following system color indexes are defined (each successive index is one larger than its predecessor):

SYSCLR_ENTRYFIELD

Entry field and list box background color.

SYSCLR_MENUDISABLEDTEXT

Entry field background color.

SYSCLR_MENUHILITE

Selected menu item text.

`SYSLR_MENUHILITEBGND`
Selected menu item background.

`SYSLR_PAGEBACKGROUND`
Notebook page background.

`SYSLR_FIELDBACKGROUND`
Inactive scroll bar and default control background color.

`SYSLR_BUTTONLIGHT`
Light push button (3D effect).

`SYSLR_BUTTONMIDDLE`
Middle push button (3D effect).

`SYSLR_BUTTONDARK`
Dark push button (3D effect).

`SYSLR_BUTTONDEFAULT`
Push button.

`SYSLR_TITLEBOTTOM`
Line drawn under title bar.

`SYSLR_SHADOW`
Drop shadow for menus and dialogs.

`SYSLR_ICONTEXT`
Text written under icons on the desktop.

`SYSLR_DIALOGBACKGROUND`
Pop up dialog box background.

`SYSLR_HILITEFOREGROUND`
Selection foreground.

`SYSLR_HILITEBACKGROUND`
Selection background.

`SYSLR_INACTIVETITLETEXTBKGD`
Background of inactive title text.

`SYSLR_ACTIVETITLETEXTBKGD`
Background of active title text.

`SYSLR_INACTIVETITLETEXT`
Inactive title text.

`SYSLR_ACTIVETITLETEXT`
Active title text.

`SYSLR_OUTPUTTEXT`
Output text.

`SYSLR_WINDOWSTATICTEXT`
Static (nonselectable) text.

`SYSLR_SCROLLBAR`
Active scroll bar background area.

`SYSLR_BACKGROUND`
Desktop background.

`SYSLR_ACTIVETITLE`
Active window title.

`SYSLR_INACTIVETITLE`
Inactive window title.

`SYSLR_MENU`
Menu background.

`SYSLR_WINDOW`

	Window background.
SYSCLR_WINDOWFRAME	Window frame (border line).
SYSCLR_MENUTEXT	Normal menu item text.
SYSCLR_WINDOWTEXT	Window text.
SYSCLR_TITLETEXT	Text in title bar, size box, scroll bar arrow box.
SYSCLR_ACTIVEBORDER	Border fill of active window.
SYSCLR_INACTIVEBORDER	Border fill of inactive window.
SYSCLR_APPWORKSPACE	Background of specific main windows.
SYSCLR_HELPBACKGROUND	Background of help panels.
SYSCLR_HELPTEXT	Help text.
SYSCLR_HELPHILITE	Highlighted help text.
SYSCLR_SHADOWHILITEBGND	Shadows of workplace object background highlight color.
SYSCLR_SHADOWHILITEFGND	Shadows of workplace object foreground highlight color.
SYSCLR_SHADOWTEXT	Shadows of workplace object text color.

WinSetSysColors Parameter - ulTablen

ulTablen ([ULONG](#)) - input
Number of elements.

Number of elements supplied in *aITable*. This may be 0 if, for example, the color table is merely to be reset to the default. For LCOLF_INDRGB it must be an even number.

WinSetSysColors Parameter - aITable

aITable ([PLONG](#)) - input
Table.

Start address of the application data area, containing the color-table definition data. The format depends on the value of *ulFormat*.

Each color value is a 4-byte integer, with a value of

$(R * 65536) + (G * 256) + B$

where:

R is red intensity value
G is green intensity value
B is blue intensity value.

There are 8 bits for each primary; the maximum intensity for each primary is 255.

WinSetSysColors Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE Successful completion
FALSE Error occurred.

WinSetSysColors - Parameters

hWndDesktop (**HWND**) - input
Desktop-window handle.

HWND_DESKTOP The desktop-window handle
Other Specified desktop-window handle.

flOptions (**ULONG**) - input
Options.

LCOL_RESET The system colors are all to be reset to default before processing the remainder of the data in this function.

LCOL_PURECOLOR Color-dithering should not be used to create colors not available in the physical palette. If this option is set, only pure colors are used and no dithering is done.

uiFormat (**ULONG**) - input
Format of entries in the table, as follows.

LCOLF_INDRGB Array of (index,RGB) values. Each pair of entries is 8-bytes long, comprising 4 bytes for the index, and 4 bytes for the color value. For system color indexes, see */Start*.

LCOLF_CONSECRGB Array of (RGB) values, corresponding to color indexes */Start* upwards. Each entry is 4-bytes long.

iStart (**LONG**) - input
Starting system color index.

This parameter is applicable only if the *uiFormat* parameter is set to LCOLF_CONSECRGB.

The number of system colors (as defined below) is given by SYSCLR_CSYS_COLORS.

The following system color indexes are defined (each successive index is one larger than its predecessor):

SYSCLR_ENTRYFIELD
Entry field and list box background color.

SYSCLR_MENUDISABLEDTEXT
Entry field background color.

SYSCLR_MENUHILITE
Selected menu item text.

SYSCLR_MENUHILITEBGND
Selected menu item background.

SYSCLR_PAGEBACKGROUND
Notebook page background.

SYSCLR_FIELDBACKGROUND
Inactive scroll bar and default control background color.

SYSCLR_BUTTONLIGHT
Light push button (3D effect).

SYSCLR_BUTTONMIDDLE
Middle push button (3D effect).

SYSCLR_BUTTONDARK
Dark push button (3D effect).

SYSCLR_BUTTONDEFAULT
Push button.

SYSCLR_TITLEBOTTOM
Line drawn under title bar.

SYSCLR_SHADOW
Drop shadow for menus and dialogs.

SYSCLR_ICONTEXT
Text written under icons on the desktop.

SYSCLR_DIALOGBACKGROUND
Pop up dialog box background.

SYSCLR_HILITEFOREGROUND
Selection foreground.

SYSCLR_HILITEBACKGROUND
Selection background.

SYSCLR_INACTIVETITLETEXTBKGD
Background of inactive title text.

SYSCLR_ACTIVETITLETEXTBKGD
Background of active title text.

SYSCLR_INACTIVETITLETEXT
Inactive title text.

SYSCLR_ACTIVETITLETEXT
Active title text.

SYSCLR_OUTPUTTEXT
Output text.

SYSCLR_WINDOWSTATICTEXT
Static (nonselectable) text.

SYSCLR_SCROLLBAR
Active scroll bar background area.

SYSLR_BACKGROUND
 Desktop background.

SYSLR_ACTIVETITLE
 Active window title.

SYSLR_INACTIVETITLE
 Inactive window title.

SYSLR_MENU
 Menu background.

SYSLR_WINDOW
 Window background.

SYSLR_WINDOWFRAME
 Window frame (border line).

SYSLR_MENUTEXT
 Normal menu item text.

SYSLR_WINDOWTEXT
 Window text.

SYSLR_TITLETEXT
 Text in title bar, size box, scroll bar arrow box.

SYSLR_ACTIVEBORDER
 Border fill of active window.

SYSLR_INACTIVEBORDER
 Border fill of inactive window.

SYSLR_APPWORKSPACE
 Background of specific main windows.

SYSLR_HELPBACKGROUND
 Background of help panels.

SYSLR_HELPTEXT
 Help text.

SYSLR_HELPHILITE
 Highlighted help text.

SYSLR_SHADOWHILITEBGND
 Shadows of workplace object background highlight color.

SYSLR_SHADOWHILITEFGND
 Shadows of workplace object foreground highlight color.

SYSLR_SHADOWTEXT
 Shadows of workplace object text color.

uiTablen (ULONG) - input
 Number of elements.

Number of elements supplied in *aTable*. This may be 0 if, for example, the color table is merely to be reset to the default. For LCOLF_INDRGB it must be an even number.

aTable (PLONG) - input
 Table.

Start address of the application data area, containing the color-table definition data. The format depends on the value of *uiFormat*.

Each color value is a 4-byte integer, with a value of

$$(R * 65536) + (G * 256) + B$$

where:

R is red intensity value
G is green intensity value
B is blue intensity value.

There are 8 bits for each primary; the maximum intensity for each primary is 255.

rc (**BOOL**) - returns
Success indicator.

TRUE Successful completion
FALSE Error occurred.

WinSetSysColors - Remarks

This function sends all main windows in the system a [WM_SYSCOLORCHANGE](#) message to indicate that the colors have changed. When this message is received, applications that depend on the system colors can query the new color values with the [WinQuerySysColor](#) function.

After the [WM_SYSCOLORCHANGE](#) messages are sent, all windows in the system are invalidated so that they are redrawn with the new system colors.

This function does *not* write any system color changes to the initialization file See

The following table gives the default RGB values for each color index:

System Color Index	Default Color	Default RGB Values
SYSCLR_ACTIVEBORDER	Pale yellow	255 255 128
SYSCLR_ACTIVETITLE	Teal	64 128 128
SYSCLR_ACTIVETITLETEXT	White	255 255 255
SYSCLR_ACTIVETITLETEXTBGND	Teal	64 128 128
SYSCLR_APPWORKSPACE	Off-white	255 255 224
SYSCLR_BACKGROUND	Light gray	204 204 204
SYSCLR_BUTTONDARK	Dark gray	128 128 128
SYSCLR_BUTTONDEFAULT	Black	0 0 0
SYSCLR_BUTTONLIGHT	White	255 255 255
SYSCLR_BUTTONMIDDLE	Light gray	204 204 204
SYSCLR_DIALOGBACKGROUND	Light gray	204 204 204
SYSCLR_ENTRYFIELD	Pale yellow	255 255 204
SYSCLR_FIELDBACKGROUND	Light gray	204 204 204
SYSCLR_HELPBACKGROUND	White	255 255 255
SYSCLR_HELPHILITE	Blue green	0 128 128
SYSCLR_HELPTEXT	Dark blue	0 0 128
SYSCLR_HILITEBACKGROUND	Dark gray	128 128 128
SYSCLR_HILITEFOREGROUND	White	255 255 255
SYSCLR_ICONTEXT	Black	0 0 0

SYSCLR_INACTIVEBORDER	Light gray	204	204	204
SYSCLR_INACTIVETITLE	Light gray	204	204	204
SYSCLR_INACTIVETITLETEXT	Dark gray	128	128	128
SYSCLR_INACTIVETITLETEXTBGND	Light gray	204	204	204
SYSCLR_MENU	Light gray	204	204	204
SYSCLR_MENUDISABLEDTEXT	Dark gray	128	128	128
SYSCLR_MENUHILITE	Black	0	0	0
SYSCLR_MENUHILITEBGND	Light grey	204	204	204
SYSCLR_MENUTEXT	Black	0	0	0
SYSCLR_OUTPUTTEXT	Black	0	0	0
SYSCLR_PAGEBACKGROUND	White	255	255	255
SYSCLR_SCROLLBAR	Pale gray	192	192	192
SYSCLR_SHADOW	Dark gray	128	128	128
SYSCLR_SHADOWHILITEBGND	Dark gray	128	128	128
SYSCLR_SHADOWHILITEFGND	White	255	255	255
SYSCLR_SHADOWTEXT	Dark gray	128	128	128
SYSCLR_TITLEBOTTOM	Dark gray	128	128	128
SYSCLR_TITLETEXT	White	255	255	255
SYSCLR_WINDOW	White	255	255	255
SYSCLR_WINDOWFRAME	Dark gray	128	128	128
SYSCLR_WINDOWSTATICTEXT	Blue	0	0	128
SYSCLR_WINDOWTEXT	Black	0	0	0

WinSetSysColors - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

PMERR_INVALID_FLAG (0x1019)
An invalid bit was set for a parameter. Use constants defined by PM for options, and do not set any reserved bits.

PMERR_PARAMETER_OUT_OF_RANGE (0x1003)
The value of a parameter was not within the defined valid range for that parameter.

WinSetSysModalWindow

WinSetSysModalWindow - Syntax

This function makes a window become the system-modal window, or ends the system-modal state.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwndDesktop; /* Desktop-window handle, or HWND_DESKTOP. */
HWND    hwnd;         /* Handle of window to become system-modal window. */
BOOL    rc;           /* Success indicator. */

rc = WinSetSysModalWindow(hwndDesktop, hwnd);
```

WinSetSysModalWindow Parameter - hwndDesktop

hwndDesktop ([HWND](#)) - input
Desktop-window handle, or HWND_DESKTOP.

WinSetSysModalWindow Parameter - hwnd

hwnd ([HWND](#)) - input
Handle of window to become system-modal window.

If NULLHANDLE, system-modal state is ended, and input processing returns to its normal state.

WinSetSysModalWindow Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinSetSysModalWindow - Parameters

hwndDesktop ([HWND](#)) - input
Desktop-window handle, or HWND_DESKTOP.

hwnd ([HWND](#)) - input
Handle of window to become system-modal window.

If NULLHANDLE, system-modal state is ended, and input processing returns to its normal state.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinSetSysModalWindow - Remarks

Input processing can enter a "system modal" state. In this state, all pointing device and keyboard input is directed to a special window, known as the system-modal window, or to one of its child windows (or a window owned by one of them). An "owned" window is a window that refers to its owner window set by using either the *hwndOwner* parameter of the [WinCreateWindow](#) function or the *hwndNewOwner* parameter of the [WinSetOwner](#) function. All other main windows behave as though they are disabled and no interaction is possible with them.

Note: The disabled windows are not actually disabled, but made noninteractive. No messages are sent to these windows when the system-modal state is entered or left, and their WS_DISABLE style bits are not changed.

Where a system-modal window exists and another window is explicitly made the active window, the newly activated window becomes the system-modal window. This replaces the old one, which becomes a noninteractive window. When the system-modal window is destroyed, the system-modal state is ended, and input processing returns to its normal state.

This function should only be called while processing pointing device or keyboard input.

The new system-modal window is **not** locked during the processing of this function.

WinSetSysModalWindow - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinSetSysPointerData

WinSetSysPointerData - Syntax

This function is specific to OS/2 Version 2.1 or higher. This function sets the given system pointer to the new icon specified by the [ICONINFO](#) structure.

```
#define INCL_WINPOINTERS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND          hwndDesktop; /* Handle to the desktop window. */
```

```
ULONG      iptr;          /* Index of the desired system pointer. */
PICONINFO  pIconInfo;     /* Icon data. */
BOOL       rc;            /* Return value. */

rc = WinSetSysPointerData(hwndDesktop, iptr,
                          pIconInfo);
```

WinSetSysPointerData Parameter - hwndDesktop

hwndDesktop ([HWND](#)) - input
Handle to the desktop window.

WinSetSysPointerData Parameter - iptr

iptr ([ULONG](#)) - input
Index of the desired system pointer.

WinSetSysPointerData Parameter - pIconInfo

pIconInfo ([PICONINFO](#)) - in/out
Icon data.

New icon data for the requested system pointer or NULL to reset the system pointer to its default appearance.

WinSetSysPointerData Return Value - rc

rc ([BOOL](#)) - returns
Return value.

TRUE	Successful.
FALSE	An error occurred.

WinSetSysPointerData - Parameters

hwndDesktop ([HWND](#)) - input
Handle to the desktop window.

iptr ([ULONG](#)) - input
Index of the desired system pointer.

plconInfo ([PICONINFO](#)) - in/out
Icon data.

New icon data for the requested system pointer or NULL to reset the system pointer to its default appearance.

rc ([BOOL](#)) - returns
Return value.

TRUE	Successful.
FALSE	An error occurred.

WinSetSysPointerData - Remarks

This function sets the given system pointer to the new icon specified by the [ICONINFO](#) structure that is passed in. Provided that the icon is valid, the screen will be refreshed with the updated system pointer if necessary.

If NULL is passed for the *plconInfo* parameter, the operating system reverts back to the default pointer shapes defined by the system. All alterations made using WinSetSysPointerData are persistent. They are preserved across IPLs of the system.

WinSetSysValue

WinSetSysValue - Syntax

This function sets a system value.

```
#define INCL_WINSYS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwndDesktop; /* Desktop-window handle. */
LONG    iSysValue;    /* System-value identity. */
LONG    lValue;       /* System value. */
BOOL    rc;           /* Value-set indicator. */

rc = WinSetSysValue(hwndDesktop, iSysValue,
                    lValue);
```

WinSetSysValue Parameter - hwndDesktop

hwndDesktop ([HWND](#)) - input
Desktop-window handle.

HWND_DESKTOP	Set the system values for the desktop-window handle
Other	Set the system values for the specified desktop-window handle.

WinSetSysValue Parameter - iSysValue

iSysValue ([LONG](#)) - input
System-value identity.

This must be one of the following `SV_*` constants that is marked with an asterisk (*).

Note: Not all system values can be set; those that can be set are marked with an asterisk (*). All of the `SV_*` constants can be queried using the [WinQuerySysValue](#).

SV_ALARM	(*) TRUE if the alarm sound generated by WinAlarm is enabled; FALSE if the alarm sound is disabled.
----------	---

SV_ALTMNEMONIC	(*) TRUE if the mnemonic is made up of KATAKANA characters; FALSE if the mnemonic is made up of ROMAN
----------------	---

characters.

SV_ANIMATION

(*) TRUE when animation is set on. FALSE when animation is set off.

SV_BEGINDRAG

(*) Mouse begin drag (low word=mouse message id (WM_*), high word=keyboard control code (KC_*)).

SV_BEGINDRAGKB

(*) Keyboard begin drag (low word=virtual key code (VK_*), high word=keyboard control code (KC_*)).

SV_BEGINSELECT

(*) Mouse begin swipe select (low word=mouse message id (WM_*), high word=keyboard control code (KC_*)).

SV_BEGINSELECTKB

(*) Keyboard begin swipe select (low word=virtual key code (VK_*), high word=keyboard control code (KC_*)).

SV_CICONTEXTLINES

(*) Maximum number of lines that the icon text may occupy for a minimized window.

SV_CONTEXTHELP

(*) Mouse control for pop-up menu (low word=mouse message id (WM_*), high word=keyboard control code (KC_*)).

SV_CONTEXTHELPKB

(*) Keyboard control for pop-up menu (low word=virtual key code (VK_*), high word=keyboard control code (KC_*)).

SV_CONTEXTMENU

(*) Mouse request pop-up menu (low word=mouse message id (WM_*), high word=keyboard control code (KC_*)).

SV_CONTEXTMENUKB

(*) Keyboard request pop-up menu (low word=virtual key code (VK_*), high word=keyboard control code (KC_*)).

SV_CMOUSEBUTTONS

The number of buttons on the pointing device (zero if no pointing device is installed).

SV_CTIMERS

Count of available timers.

SV_CURSORLEVEL

The cursor hide level.

SV_CURSORRATE

(*) Cursor blink rate, in milliseconds.

SV_CXBORDER

Width of the nominal-width border.

SV_CXBYTEALIGN

Horizontal count of pels for alignment.

SV_CXDBLCLK

(*) Width of the pointing device double-click sensitive area. The default is the system-font character width.

SV_CXDLGFRAME

Width of the dialog-frame border.

SV_CXFULLSCREEN

Width of the client area when the window is full screen.

SV_CXHSCROLLARROW

Width of the horizontal scroll-bar arrow bit maps.

SV_CXHSLIDER

Width of the horizontal scroll-bar thumb.

SV_CXICON

Icon width.

SV_CXICONTEXTWIDTH

(*) Maximum number of characters per line allowed in the icon text for a minimized window.

SV_CXMINMAXBUTTON
Width of the minimize/maximize buttons.

SV_CXMOTIONSTART
(*) The number of pels that a pointing device must be moved in the horizontal direction, while the button is depressed, before a WM_BUTTONxMOTIONSTR message is sent.

SV_CXPOINTER
Pointer width.

SV_CXSCREEN
Width of the screen.

SV_CXSIZEBORDER
(*) Width of the sizing border.

SV_CXVSCROLL
Width of the vertical scroll-bar.

SV_CYBORDER
Height of the nominal-width border.

SV_CYBYTEALIGN
Vertical count of pels for alignment.

SV_CYDBLCLK
(*) Height of the pointing device double-click sensitive area. The default is half the height of the system font character height.

SV_CYDLGFRAME
Height of the dialog-frame border.

SV_CYFULLSCREEN
Height of the client area when the window is full screen (excluding menu height).

SV_CYHSCROLL
Height of the horizontal scroll-bar.

SV_CYICON
Icon height.

SV_CYMENU
Height of the single-line menu height.

SV_CYMINMAXBUTTON
Height of the minimize/maximize buttons.

SV_CYMOTIONSTART
(*) The number of pels that a pointing device must be moved in the vertical direction, while the button is depressed, before a WM_BUTTONxMOTIONSTR message is sent.

SV_CYPOINTER
Pointer height.

SV_CYSCREEN
Height of the screen.

SV_CYSIZEBORDER
(*) Height of the sizing border.

SV_CYTITLEBAR
Height of the caption.

SV_CYVSCROLLARROW
Height of the vertical scroll-bar arrow bit maps.

SV_CYVSLIDER
Height of the vertical scroll-bar thumb.

SV_DBLCLKTIME
(*) Pointing device double-click time, in milliseconds.

SV_DEBUG

FALSE indicates this is not a debug system.

SV_ENDDRAG

(*) Mouse end drag (low word=mouse message id (WM_*), high word=keyboard control code (KC_*)).

SV_ENDDRAGKB

(*) Keyboard end drag (low word=virtual key code (VK_*), high word=keyboard control code (KC_*)).

SV_ENDSELECT

(*) Mouse select or end swipe select (low word=mouse message id (WM_*), high word=keyboard control code (KC_*)).

SV_ENDSELECTKB

(*) Keyboard select or end swipe select (low word=virtual key code (VK_*), high word=keyboard control code (KC_*)).

SV_ERRORDURATION

(*) Duration for error alarms generated by [WinAlarm](#).

SV_ERRORFREQ

(*) Frequency for error alarms generated by [WinAlarm](#).

SV_EXTRAKEYBEEP

(*) When TRUE, the press of a key that does not exist on the Enhanced keyboard causes the system to generate a beep.

SV_FIRSTSCROLLRATE

(*) The delay (in milliseconds) before autoscrolling starts, when using a scroll bar.

SV_INSERTMODE

(*) TRUE if the system is in insert mode (for edit and multi-line edit controls); FALSE if in overwrite mode.

This system value is toggled by the system when the insert key is toggled, regardless of which window has the focus at the time.

SV_KBDALTERED

(*) Hardware ID of the newly attached keyboard.

Note: The OS/2 National Language Support is only loaded once per system IPL. The OS/2 NLS translation is based partially on the type of keyboard device attached to the system. There are two main keyboard device types: PC AT styled and Enhanced styled. Hot Plugging between these two types of devices may result in typing anomalies due to a mismatch in the NLS device tables loaded and that of the attached device. It is strongly recommended that keyboard hot plugging be limited to the device type that the system was IPL'd with. In addition, OS/2 support will default to the 101/102 key Enhanced keyboard if no keyboard or a NetServer Mode password was in use during system IPL. (See Category 4, IOCTls 77h and 7Ah for more information on keyboard devices and types.)

SV_LOCKSTARTINPUT

(*) TRUE when the type ahead function is enabled; FALSE when the type ahead function is disabled.

SV_MENUROLLOLDOWNDELAY

(*) The delay in milliseconds before displaying a pull down referred to from a submenu item, when the button is already down as the pointer moves onto the submenu item.

SV_MENUROLLUPDELAY

(*) The delay in milliseconds before hiding a pull down referred to from a submenu item, when the button is already down as the pointer moves off the submenu item.

SV_MONOICONS

(*) When TRUE preference is given to black and white icons when selecting which icon resource definition to use on the screen. Black and white icons may have more clarity than color icons on LCD and Plasma display screens.

SV_MOUSEPRESENT

When TRUE a mouse pointing device is attached to the system.

SV_NOTEDURATION

(*) Duration for note alarms generated by [WinAlarm](#).

SV_NOTEFREQ

(*) Frequency for note alarms generated by [WinAlarm](#).

SV_OPEN

(*) Mouse open (low word=mouse message id (WM_*), high word=keyboard control code (KC_*)).

SV_OPENKB
 (*) Keyboard open (low word=virtual key code (VK_*), high word=keyboard control code (KC_*)).

SV_POINTERLEVEL
 Pointer hide level. If the pointer level is zero, the pointer is visible. If it is greater than zero, the pointer is not visible. The [WinShowPointer](#) call is invoked to increment and decrement the SV_POINTERLEVEL, but its value cannot become negative.

SV_PRINTSCREEN
 (*) TRUE when the Print Screen function is enabled; FALSE when the Print Screen function is disabled.

SV_SCROLLRATE
 (*) The delay (in milliseconds) between scroll operations, when using a scroll bar.

SV_SETLIGHTS
 (*) When TRUE, the appropriate light is set when the keyboard state table is set.

SV_SINGLESELECT
 (*) Mouse select (low word=mouse message id (WM_*), high word=keyboard control code (KC_*)).

SV_TASKLISTMOUSEACCESS
 (*) Determines whether the task list is displayed when mouse buttons 1 and 2 are pressed simultaneously, or when mouse button 2 is pressed by itself, or for no mouse gesture.

SV_TEXTEDIT
 (*) Mouse begin direct name edit (low word=mouse message id (WM_*), high word=keyboard control code (KC_*)).

SV_TEXTEDITKB
 (*) Keyboard begin direct name edit (low word=virtual key code (VK_*), high word=keyboard control code (KC_*)).

SV_TRACKRECTLEVEL
 The hide level of the tracking rectangle (zero if visible, greater than zero if not).

SV_SWAPBUTTON
 (*) TRUE if pointing device buttons are swapped. Normally, the pointing device buttons are set for right-handed use. Setting this value changes them for left-handed use.

If TRUE, WM_LBUTTONDOWN* messages are returned when the user presses the right button, and WM_RBUTTONDOWN* messages are returned when the left button is pressed. Modifying this value affects the entire system. Applications should not normally read or set this value; users update this value by means of the user interface shell to suit their requirements.

SV_WARNINGDURATION
 (*) Duration for warning alarms generated by [WinAlarm](#).

SV_WARNINGFREQ
 (*) Frequency for warning alarms generated by [WinAlarm](#).

WinSetSysValue Parameter - IValue

IValue ([LONG](#)) - input
 System value.

Dimensions are in pels and times are in milliseconds.

WinSetSysValue Return Value - rc

rc (**BOOL**) - returns
Value-set indicator.

TRUE	System value set.
FALSE	Error occurred.

WinSetSysValue - Parameters

hwndDesktop (**HWND**) - input
Desktop-window handle.

HWND_DESKTOP	Set the system values for the desktop-window handle
Other	Set the system values for the specified desktop-window handle.

iSysValue (**LONG**) - input
System-value identity.

This must be one of the following SV_* constants that is marked with an asterisk (*).

Note: Not all system values can be set; those that can be set are marked with an asterisk (*). All of the SV_* constants can be queried using the [WinQuerySysValue](#).

SV_ALARM	(*) TRUE if the alarm sound generated by WinAlarm is enabled; FALSE if the alarm sound is disabled.
SV_ALTMNEMONIC	(*) TRUE if the mnemonic is made up of KATAKANA characters; FALSE if the mnemonic is made up of ROMAN characters.
SV_ANIMATION	(*) TRUE when animation is set on. FALSE when animation is set off.
SV_BEGINDRAG	(*) Mouse begin drag (low word=mouse message id (WM_*), high word=keyboard control code (KC_*)).
SV_BEGINDRAGKB	(*) Keyboard begin drag (low word=virtual key code (VK_*), high word=keyboard control code (KC_*)).
SV_BEGINSELECT	(*) Mouse begin swipe select (low word=mouse message id (WM_*), high word=keyboard control code (KC_*)).
SV_BEGINSELECTKB	(*) Keyboard begin swipe select (low word=virtual key code (VK_*), high word=keyboard control code (KC_*)).
SV_CICONTEXTLINES	(*) Maximum number of lines that the icon text may occupy for a minimized window.
SV_CONTEXTHELP	(*) Mouse control for pop-up menu (low word=mouse message id (WM_*), high word=keyboard control code (KC_*)).
SV_CONTEXTHELPKB	(*) Keyboard control for pop-up menu (low word=virtual key code (VK_*), high word=keyboard control code (KC_*)).
SV_CONTEXTMENU	(*) Mouse request pop-up menu (low word=mouse message id (WM_*), high word=keyboard control code (KC_*)).
SV_CONTEXTMENUKB	(*) Keyboard request pop-up menu (low word=virtual key code (VK_*), high word=keyboard control code (KC_*)).

SV_CMOUSEBUTTONS
The number of buttons on the pointing device (zero if no pointing device is installed).

SV_CTIMERS
Count of available timers.

SV_CURSORLEVEL
The cursor hide level.

SV_CURSRRATE
(*) Cursor blink rate, in milliseconds.

SV_CXBORDER
Width of the nominal-width border.

SV_CXBYTEALIGN
Horizontal count of pels for alignment.

SV_CXDBLCLK
(*) Width of the pointing device double-click sensitive area. The default is the system-font character width.

SV_CXDLGFRAME
Width of the dialog-frame border.

SV_CXFULLSCREEN
Width of the client area when the window is full screen.

SV_CXHSCROLLARROW
Width of the horizontal scroll-bar arrow bit maps.

SV_CXHSLIDER
Width of the horizontal scroll-bar thumb.

SV_CXICON
Icon width.

SV_CXICONTEXTWIDTH
(*) Maximum number of characters per line allowed in the icon text for a minimized window.

SV_CXMINMAXBUTTON
Width of the minimize/maximize buttons.

SV_CXMOTIONSTART
(*) The number of pels that a pointing device must be moved in the horizontal direction, while the button is depressed, before a WM_BUTTONNxmOTIONSTR message is sent.

SV_CXPOINTER
Pointer width.

SV_CXSCREEN
Width of the screen.

SV_CXSIZEBORDER
(*) Width of the sizing border.

SV_CXVSCROLL
Width of the vertical scroll-bar.

SV_CYBORDER
Height of the nominal-width border.

SV_CYBYTEALIGN
Vertical count of pels for alignment.

SV_CYDBLCLK
(*) Height of the pointing device double-click sensitive area. The default is half the height of the system font character height.

SV_CYDLGFRAME
Height of the dialog-frame border.

SV_CYFULLSCREEN
Height of the client area when the window is full screen (excluding menu height).

SV_CYHSCROLL
Height of the horizontal scroll-bar.

SV_CYICON
Icon height.

SV_CYMENU
Height of the single-line menu height.

SV_CYMINMAXBUTTON
Height of the minimize/maximize buttons.

SV_CYMOTIONSTART
(*) The number of pels that a pointing device must be moved in the vertical direction, while the button is depressed, before a WM_BUTTONxMOTIONSTR message is sent.

SV_CYPOINTER
Pointer height.

SV_CYSCREEN
Height of the screen.

SV_CYSIZEBORDER
(*) Height of the sizing border.

SV_CYTITLEBAR
Height of the caption.

SV_CYVSCROLLARROW
Height of the vertical scroll-bar arrow bit maps.

SV_CYVSLIDER
Height of the vertical scroll-bar thumb.

SV_DBLCLKTIME
(*) Pointing device double-click time, in milliseconds.

SV_DEBUG
FALSE indicates this is not a debug system.

SV_ENDDRAG
(*) Mouse end drag (low word=mouse message id (WM_*), high word=keyboard control code (KC_*)).

SV_ENDDRAGKB
(*) Keyboard end drag (low word=virtual key code (VK_*), high word=keyboard control code (KC_*)).

SV_ENDSELECT
(*) Mouse select or end swipe select (low word=mouse message id (WM_*), high word=keyboard control code (KC_*)).

SV_ENDSELECTKB
(*) Keyboard select or end swipe select (low word=virtual key code (VK_*), high word=keyboard control code (KC_*)).

SV_ERRORDURATION
(*) Duration for error alarms generated by [WinAlarm](#).

SV_ERRORFREQ
(*) Frequency for error alarms generated by [WinAlarm](#).

SV_EXTRAKEYBEEP
(*) When TRUE, the press of a key that does not exist on the Enhanced keyboard causes the system to generate a beep.

SV_FIRSTSCROLLRATE
(*) The delay (in milliseconds) before autoscrolling starts, when using a scroll bar.

SV_INSERTMODE
(*) TRUE if the system is in insert mode (for edit and multi-line edit controls); FALSE if in overwrite mode.

This system value is toggled by the system when the insert key is toggled, regardless of which window has the focus at the time.

SV_KBDALTERED

(*) Hardware ID of the newly attached keyboard.

Note: The OS/2 National Language Support is only loaded once per system IPL. The OS/2 NLS translation is based partially on the type of keyboard device attached to the system. There are two main keyboard device types: PC AT styled and Enhanced styled. Hot Plugging between these two types of devices may result in typing anomalies due to a mismatch in the NLS device tables loaded and that of the attached device. It is strongly recommended that keyboard hot plugging be limited to the device type that the system was IPL'd with. In addition, OS/2 support will default to the 101/102 key Enhanced keyboard if no keyboard or a NetServer Mode password was in use during system IPL. (See Category 4, IOCTls 77h and 7Ah for more information on keyboard devices and types.)

SV_LOCKSTARTINPUT

(*) TRUE when the type ahead function is enabled; FALSE when the type ahead function is disabled.

SV_MENUROLLOLDOWNDELAY

(*) The delay in milliseconds before displaying a pull down referred to from a submenu item, when the button is already down as the pointer moves onto the submenu item.

SV_MENUROLLUPDELAY

(*) The delay in milliseconds before hiding a pull down referred to from a submenu item, when the button is already down as the pointer moves off the submenu item.

SV_MONOICONS

(*) When TRUE preference is given to black and white icons when selecting which icon resource definition to use on the screen. Black and white icons may have more clarity than color icons on LCD and Plasma display screens.

SV_MOUSEPRESENT

When TRUE a mouse pointing device is attached to the system.

SV_NOTEDURATION

(*) Duration for note alarms generated by [WinAlarm](#).

SV_NOTEFREQ

(*) Frequency for note alarms generated by [WinAlarm](#).

SV_OPEN

(*) Mouse open (low word=mouse message id (WM_*), high word=keyboard control code (KC_*)).

SV_OPENKB

(*) Keyboard open (low word=virtual key code (VK_*), high word=keyboard control code (KC_*)).

SV_POINTERLEVEL

Pointer hide level. If the pointer level is zero, the pointer is visible. If it is greater than zero, the pointer is not visible. The [WinShowPointer](#) call is invoked to increment and decrement the SV_POINTERLEVEL, but its value cannot become negative.

SV_PRINTSCREEN

(*) TRUE when the Print Screen function is enabled; FALSE when the Print Screen function is disabled.

SV_SCROLLRATE

(*) The delay (in milliseconds) between scroll operations, when using a scroll bar.

SV_SETLIGHTS

(*) When TRUE, the appropriate light is set when the keyboard state table is set.

SV_SINGLESELECT

(*) Mouse select (low word=mouse message id (WM_*), high word=keyboard control code (KC_*)).

SV_TASKLISTMOUSEACCESS

(*) Determines whether the task list is displayed when mouse buttons 1 and 2 are pressed simultaneously, or when mouse button 2 is pressed by itself, or for no mouse gesture.

SV_TEXTEDIT

(*) Mouse begin direct name edit (low word=mouse message id (WM_*), high word=keyboard control code (KC_*)).

SV_TEXTEDITKB

(*) Keyboard begin direct name edit (low word=virtual key code (VK_*), high word=keyboard control code (KC_*)).

SV_TRACKRECTLEVEL

The hide level of the tracking rectangle (zero if visible, greater than zero if not).

SV_SWAPBUTTON

(*) TRUE if pointing device buttons are swapped. Normally, the pointing device buttons are set for right-handed use. Setting this value changes them for left-handed use.

If TRUE, WM_LBUTTONDOWN* messages are returned when the user presses the right button, and WM_RBUTTONDOWN* messages are returned when the left button is pressed. Modifying this value affects the entire system. Applications should not normally read or set this value; users update this value by means of the user interface shell to suit their requirements.

SV_WARNINGDURATION

(*) Duration for warning alarms generated by [WinAlarm](#).

SV_WARNINGFREQ

(*) Frequency for warning alarms generated by [WinAlarm](#).

IValue ([LONG](#)) - input
System value.

Dimensions are in pels and times are in milliseconds.

rc ([BOOL](#)) - returns
Value-set indicator.

TRUE

System value set.

FALSE

Error occurred.

WinSetSysValue - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

PMERR_PARAMETER_OUT_OF_RANGE (0x1003)
The value of a parameter was not within the defined valid range for that parameter.

WinSetSysValue - Example Code

This example uses the WinSetSysValue call change the sizing border dimensions.

```
#define INCL_WINSYS
#include <OS2.H>
LONG vlXBorder, vlYBorder;

vlXBorder = WinSetSysValue(HWND_DESKTOP,
```

```
        SV_CXSIZEBORDER,  
        20L);  
vlyBorder = WinSetSysValue(HWND_DESKTOP,  
        SV_CYSIZEBORDER,  
        20L);
```

WinSetVisibleRegionNotify

WinSetVisibleRegionNotify - Syntax

This function allows an application to request that a given window receive notifications every time that its visible region gets altered.

```
#define INCL_WINMESSAGEGR /* Or use INCL_WIN, INCL_PM, */  
#include <os2.h>  
  
HWND    hwnd;        /* The window handle. */  
BOOL    fEnable;     /* Enable flag. */  
BOOL    fSuccess;     /* Success indicator. */  
  
fSuccess = WinSetVisibleRegionNotify(hwnd,  
        fEnable);
```

WinSetVisibleRegionNotify Parameter - hwnd

hwnd ([HWND](#)) - input
The window handle.

WinSetVisibleRegionNotify Parameter - fEnable

fEnable (BOOL) - input
Enable flag.

TRUE

The specified window wants to receive notifications every time its visible region is modified.

FALSE

The specified window no longer wants to receive any notification messages concerning its visible region.

WinSetVisibleRegionNotify Return Value - fSuccess

fSuccess (BOOL) - returns
Success indicator.

TRUE

Successful completion

FALSE

Error occurred.

WinSetVisibleRegionNotify - Parameters

hwnd (HWND) - input
The window handle.

fEnable (BOOL) - input
Enable flag.

TRUE

The specified window wants to receive notifications every time its visible region is modified.

FALSE

The specified window no longer wants to receive any notification messages concerning its visible region.

fSuccess (BOOL) - returns
Success indicator.

TRUE

Successful completion

FALSE

Error occurred.

WinSetVisibleRegionNotify - Remarks

This call causes a notification message to be sent to the specified window every time its visible area is modified on the screen. In addition, the window is notified when an application issues a [WinLockWindowUpdate](#) call that affects it, so that any asynchronous drawing activity can be suspended.

Applications that blit to the screen memory directly can use the notification messages [WM_VRNEENABLED](#) and [WM_VRNDISABLED](#) to determine when to suspend blitting and also to determine when the clipping areas for the visible region have been modified.

Use [WinQueryVisibleRegion](#) to obtain the current visible region when a window is notified that its visible region has changed.

WinSetWindowBits

WinSetWindowBits - Syntax

This function sets a number of bits into the memory of the reserved window words.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND     hwnd; /* Window handle. */
LONG     index; /* Zero-based index of the value to be set. */
ULONG    flData; /* Bit data to store in the window words. */
ULONG    flMask; /* Bits to be written indicator. */
BOOL     rc; /* Success indicator. */

rc = WinSetWindowBits(hwnd, index, flData,
    flMask);
```

WinSetWindowBits Parameter - hwnd

hwnd ([HWND](#)) - input
Window handle.

WinSetWindowBits Parameter - index

index ([LONG](#)) - input
Zero-based index of the value to be set.

The units of *index* are bytes. Valid values are zero through (*cbWindowData* -4), where *cbWindowData* is the parameter in [WinRegisterClass](#) that specifies the number of bytes available for application-defined storage. Any of the following QWL_* values can be specified:

QWL_HMQ	Handle of message queue of window. Note that the leading 16 bits of this value are zero.
QWL_STYLE	Window style.
QWL_HWNDFOCUSSAVE	Window handle of the child windows of this window that last possessed the focus when this frame window was last deactivated.
QWL_USER	<p>A ULONG value for applications to use is present at offset QWL_USER in windows of the following preregistered window classes:</p> <div>WC_FRAME (includes dialog windows) WC_COMBOBOX WC_BUTTON WC_MENU WC_STATIC WC_ENTRYFIELD WC_LISTBOX WC_SCROLLBAR WC_TITTLEBAR WC_MLE WC_SPINBUTTON WC_CONTAINER WC_SLIDER WC_VALUESET WC_NOTEBOOK</div> <p>This value can be used to place application-specific data in controls.</p>
QWL_DEFBUTTON	<p>The default push button for a dialog.</p> <p>The default push button is the one that sends its WM_COMMAND message when the enter key is pressed.</p>
QWL_PENDATA	Reserved for use by operating system extensions. It allows an operating system extension to store data on a per window basis.
Other	Zero-based index.

WinSetWindowBits Parameter - flData

flData (ULONG) - input
Bit data to store in the window words.

This is done under the control of the *flMask* parameter.

WinSetWindowBits Parameter - flMask

flMask (ULONG) - input
Bits to be written indicator.

A "1" bit indicates that the corresponding bit of the *flData* parameter is to be stored into the window word. A "0" bit indicates that the corresponding bit of the *flData* parameter is to be ignored in the storing operation; the value of that bit position in the window word is unaltered.

WinSetWindowBits Return Value - rc

rc (BOOL) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinSetWindowBits - Parameters

hwnd (HWND) - input
Window handle.

index (LONG) - input
Zero-based index of the value to be set.

The units of *index* are bytes. Valid values are zero through (*cbWindowData* -4), where *cbWindowData* is the parameter in [WinRegisterClass](#) that specifies the number of bytes available for application-defined storage. Any of the following QWL_* values can be specified:

QWL_HMQ	Handle of message queue of window. Note that the leading 16 bits of this value are zero.
QWL_STYLE	Window style.
QWL_HWNDFOCUSSAVE	Window handle of the child windows of this window that last possessed the focus when this frame window was last deactivated.
QWL_USER	A ULONG value for applications to use is present at offset QWL_USER in windows of the following preregistered window classes: WC_FRAME (includes dialog windows)

WC_COMBOBOX
WC_BUTTON
WC_MENU
WC_STATIC
WC_ENTRYFIELD
WC_LISTBOX
WC_SCROLLBAR
WC_TITTLBAR
WC_MLE
WC_SPINBUTTON
WC_CONTAINER
WC_SLIDER
WC_VALUESET
WC_NOTEBOOK

This value can be used to place application-specific data in controls.

QWL_DEFBUTTON

The default push button for a dialog.

The default push button is the one that sends its [WM_COMMAND](#) message when the enter key is pressed.

QWL_PENDATA

Reserved for use by operating system extensions. It allows an operating system extension to store data on a per window basis.

Other

Zero-based index.

flData ([ULONG](#)) - input

Bit data to store in the window words.

This is done under the control of the *flMask* parameter.

flMask ([ULONG](#)) - input

Bits to be written indicator.

A "1" bit indicates that the corresponding bit of the *flData* parameter is to be stored into the window word. A "0" bit indicates that the corresponding bit of the *flData* parameter is to be ignored in the storing operation; the value of that bit position in the window word is unaltered.

rc ([BOOL](#)) - returns

Success indicator.

TRUE

Successful completion

FALSE

Error occurred.

WinSetWindowBits - Remarks

The bits are set in a single operation.

WinSetWindowBits - Example Code

This example uses the WinSetWindowBits call to change the attributes of a list box so that only one item can be selected. This is done by turning off the multiple-select bit.

```
#define INCL_WINSYS
#include <OS2.H>
HWND hwndMessageLB;
WinSetWindowBits(hwndMessageLB,
    QWL_STYLE,          /* change style bit. */
    0L,                 /* set to 0. */
    LS_MULTIPLESEL);    /* multiple select bit. */
```

WinSetWindowPos

WinSetWindowPos - Syntax

This function allows the general positioning of a window.

Note: Messages may be received from other processes or threads during the processing of this function.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwnd;          /* Window handle. */
HWND    hwndInsertBehind; /* Relative window-placement order. */
LONG    x;             /* Window position, x-coordinate. */
LONG    y;             /* Window position, y-coordinate. */
LONG    cx;            /* Window size. */
```

```

LONG      cy;                /* Window size. */
ULONG     fl;                /* Window-positioning options. */
BOOL      rc;                /* Repositioning indicator. */

rc = WinSetWindowPos(hwnd, hwndInsertBehind,
    x, y, cx, cy, fl);

```

WinSetWindowPos Parameter - hwnd

hwnd (**HWND**) - input
Window handle.

WinSetWindowPos Parameter - hwndInsertBehind

hwndInsertBehind (**HWND**) - input
Relative window-placement order.

Ignored if SWP_ZORDER is not selected. Values that can be specified are:

HWND_TOP	Place <i>hwnd</i> on top of all siblings
HWND_BOTTOM	Place <i>hwnd</i> behind all siblings
Other	Identifies the sibling window behind which <i>hwnd</i> is to be placed.

WinSetWindowPos Parameter - x

x (**LONG**) - input
Window position, x-coordinate.

This is the x-coordinate of *hwnd*. It is in window coordinates relative to the bottom left corner of its parent, but is ignored if SWP_MOVE is not selected.

WinSetWindowPos Parameter - y

y (**LONG**) - input
Window position, y-coordinate.

This is the y-coordinate of *hwnd*. It is in window coordinates relative to the bottom left corner of its parent, but is ignored if SWP_MOVE is not selected.

WinSetWindowPos Parameter - cx

cx ([LONG](#)) - input
Window size.

This specifies the width of *hwnd* in device units, but is ignored if SWP_SIZE is not selected.

WinSetWindowPos Parameter - cy

cy ([LONG](#)) - input
Window size.

This specifies the depth of *hwnd* in device units, but is ignored if SWP_SIZE is not selected.

WinSetWindowPos Parameter - fl

fl ([ULONG](#)) - input
Window-positioning options.

One or more of these options can be specified:

- SWP_SIZE

Change the window size.
- SWP_MOVE

Change the window x,y position.
- SWP_ZORDER

Change the relative window placement.
- SWP_SHOW

Show the window.
- SWP_HIDE

Hide the window.
- SWP_NOREDRAW

Changes are not redrawn.
- SWP_NOADJUST

Do not send a [WM_ADJUSTWINDOWPOS](#) message before moving or sizing.
- SWP_ACTIVATE

Activate the *hwnd* window if it is a frame window. This indicator has no effect on other windows.

The frame window is made the topmost window, unless SWP_ZORDER is specified also in which instance the *hwndInsertBehind* window is used.
- SWP_DEACTIVATE

Deactivate the *hwnd* window if it is a frame window. This indicator has no effect on other windows.

The frame window is made the bottommost window, unless SWP_ZORDER is specified, in which instance the

hwndInsertBehind window is used.

SWP_MINIMIZE

Minimize the window. This indicator has no effect if the window is in a minimized state, and is also mutually exclusive with SWP_MAXIMIZE and SWP_RESTORE.

SWP_MAXIMIZE

Maximize the window. This indicator has no effect if the window is in a maximized state, and is also mutually exclusive with SWP_MINIMIZE and SWP_RESTORE.

SWP_RESTORE

Restore the window. This indicator has no effect if the window is in its normal state, and is also mutually exclusive with SWP_MINIMIZE and SWP_MAXIMIZE.

The position and size of the window in its normal state is remembered in its window words when it is first maximized or minimized, although these values can be altered by use of the [WinSetWindowUShort](#) function.

The window is restored to the position and size remembered in its window words, unless the SWP_MOVE or SWP_SIZE indicators are set. These indicators cause the position and size values specified in this function to be used.

WinSetWindowPos Return Value - rc

rc ([BOOL](#)) - returns
Repositioning indicator.

TRUE

Window successfully repositioned

FALSE

Window not successfully repositioned.

WinSetWindowPos - Parameters

hwnd ([HWND](#)) - input
Window handle.

hwndInsertBehind ([HWND](#)) - input
Relative window-placement order.

Ignored if SWP_ZORDER is not selected. Values that can be specified are:

HWND_TOP

Place *hwnd* on top of all siblings

HWND_BOTTOM

Place *hwnd* behind all siblings

Other

Identifies the sibling window behind which *hwnd* is to be placed.

x ([LONG](#)) - input
Window position, x-coordinate.

This is the x-coordinate of *hwnd*. It is in window coordinates relative to the bottom left corner of its parent, but is ignored if SWP_MOVE is not selected.

y ([LONG](#)) - input
Window position, y-coordinate.

This is the y-coordinate of *hwnd*. It is in window coordinates relative to the bottom left corner of its parent, but is ignored if

SWP_MOVE is not selected.

cx (**LONG**) - input
Window size.

This specifies the width of *hwnd* in device units, but is ignored if SWP_SIZE is not selected.

cy (**LONG**) - input
Window size.

This specifies the depth of *hwnd* in device units, but is ignored if SWP_SIZE is not selected.

fl (**ULONG**) - input
Window-positioning options.

One or more of these options can be specified:

SWP_SIZE
Change the window size.

SWP_MOVE
Change the window x,y position.

SWP_ZORDER
Change the relative window placement.

SWP_SHOW
Show the window.

SWP_HIDE
Hide the window.

SWP_NOREDRAW
Changes are not redrawn.

SWP_NOADJUST
Do not send a [WM_ADJUSTWINDOWPOS](#) message before moving or sizing.

SWP_ACTIVATE
Activate the *hwnd* window if it is a frame window. This indicator has no effect on other windows.

The frame window is made the topmost window, unless SWP_ZORDER is specified also in which instance the *hwndInsertBehind* window is used.

SWP_DEACTIVATE
Deactivate the *hwnd* window if it is a frame window. This indicator has no effect on other windows.

The frame window is made the bottommost window, unless SWP_ZORDER is specified, in which instance the *hwndInsertBehind* window is used.

SWP_MINIMIZE
Minimize the window. This indicator has no effect if the window is in a minimized state, and is also mutually exclusive with SWP_MAXIMIZE and SWP_RESTORE.

SWP_MAXIMIZE
Maximize the window. This indicator has no effect if the window is in a maximized state, and is also mutually exclusive with SWP_MINIMIZE and SWP_RESTORE.

SWP_RESTORE
Restore the window. This indicator has no effect if the window is in its normal state, and is also mutually exclusive with SWP_MINIMIZE and SWP_MAXIMIZE.

The position and size of the window in its normal state is remembered in its window words when it is first maximized or minimized, although these values can be altered by use of the [WinSetWindowUShort](#) function.

The window is restored to the position and size remembered in its window words, unless the SWP_MOVE or SWP_SIZE indicators are set. These indicators cause the position and size values specified in this function to be used.

rc (**BOOL**) - returns
Repositioning indicator.

TRUE

FALSE	Window successfully repositioned
	Window not successfully repositioned.

WinSetWindowPos - Remarks

If a window created with the CS_SAVEBITS style is reduced, the screen image saved is used to redraw the area uncovered when the window size changes, if those bits are still valid.

If the CS_SIZEREDRAW style is present, the entire window area is assumed invalid if sized. Otherwise, [WM_CALCVALIDRECTS](#) is sent to the window to inform the window manager which bits it may be possible to preserve.

Messages sent from WinSetWindowPos and [WinSetMultWindowPos](#) have specific orderings within the window-positioning process. The process begins with redundancy checks and precalculations on every window for each requested operation. For example, if SWP_SHOW is present but the window is already visible, SWP_SHOW is turned off. If SWP_SIZE is present, and the new size is equal to the old size, SWP_SIZE is turned off.

If the operations create new results, the information is calculated and stored (for instance, when sizing or moving, the new window rectangle is stored for later use). It is at this point that the [WM_ADJUSTWINDOWPOS](#) message is sent to any window that is sizing or moving. It is also at this point that the [WM_CALCVALIDRECTS](#) message is sent to any window that is sizing and does not have the CS_SIZEREDRAW window style.

When all the new window states are calculated, the window-management process begins. Window areas that can be preserved are moved from the old to the new positions, window areas that are invalidated by these operations are calculated and distributed as update regions. When this is finished, and before any synchronous-paint windows are repainted, the [WM_SIZE](#) message is sent to any windows that have changed size. Next, all the synchronous-paint windows that can be are repainted, and the process is complete.

If a synchronous-paint parent window has a size-sensitive area displayed that includes synchronous-paint child windows, the parent needs to reposition those windows when it receives the [WM_SIZE](#) message. Their invalid regions are added to the parent's invalid region, resulting in one update after the parent's [WM_SIZE](#) message, rather than many independent (and later, duplicated) updates.

Note: Some windows will not be positioned precisely to the parameters of this function, but according to the behavior of their window procedure. For example, frame windows without a style creation flag of FCF_NOBYTEALIGN will not position to any specific screen coordinate. Similarly, frame windows with zero size and position are created by the [WinCreateStdWindow](#) function and therefore these values are treated as a special case by the frame window procedure.

Messages sent by this function are:

[WM_ACTIVATE](#)

Sent if a different window becomes the active window. See also [WinSetActiveWindow](#).

[WM_ADJUSTWINDOWPOS](#)

Not sent if SWP_NOADJUST is specified. The message contains an SWP structure that has been filled in by this function with the proposed move/size data. The window can adjust this new position by changing the contents of the [SWP](#) structure. If *hwnd* specifies a frame window, this function recalculates the sizes and positions of the frame controls. If the new window rectangle for any frame control is empty, instead of resizing or repositioning that control, it is hidden if SWP_HIDE is specified. This eliminates needless processing of windows that are not visible. The window rectangle of the control in question is left in its original state. For example, if WinSetWindowPos is issued to change the size of a standard-frame window to an empty rectangle, and [WinQueryWindowRect](#) is issued against the client window, the rectangle returned is not an empty rectangle, but the original client rectangle before WinSetWindowPos was issued.

[WM_CALCVALIDRECTS](#)

Sent to determine the area of a window that may be possible to preserve as the window is sized.

[WM_SIZE](#)

Sent if the size of the window has changed, after the change has been made.

[WM_MOVE](#)

Sent when a window with CS_MOVENOTIFY class style moves its absolute position.

WinSetWindowPos - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

PMERR_INVALID_FLAG (0x1019)
An invalid bit was set for a parameter. Use constants defined by PM for options, and do not set any reserved bits.

WinSetWindowPtr

WinSetWindowPtr - Syntax

This function sets a pointer value into the memory of the reserved window words.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND     hwnd; /* Window handle. */
LONG     lb; /* Zero-based index into the window words. */
PVOID     pp; /* Pointer value to store in the window words. */
BOOL     rc; /* Success indicator. */

rc = WinSetWindowPtr(hwnd, lb, pp);
```

WinSetWindowPtr Parameter - hwnd

hwnd ([HWND](#)) - input
Window handle.

WinSetWindowPtr Parameter - lb

lb (**LONG**) - input
Zero-based index into the window words.

The units of b are bytes. Valid values are zero through (*cbWindowData* -4), where *cbWindowData* is the parameter in [WinRegisterClass](#) that specifies the number of bytes available for application-defined storage.

The value QWP_PFNWP can be used as the index for the address of the window procedure for the window.

WinSetWindowPtr Parameter - pp

pp (**PVOID**) - input
Pointer value to store in the window words.

WinSetWindowPtr Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinSetWindowPtr - Parameters

hwnd (**HWND**) - input
Window handle.

lb (**LONG**) - input
Zero-based index into the window words.

The units of b are bytes. Valid values are zero through (*cbWindowData* -4), where *cbWindowData* is the parameter in [WinRegisterClass](#) that specifies the number of bytes available for application-defined storage.

The value QWP_PFNWP can be used as the index for the address of the window procedure for the window.

pp (**PVOID**) - input
Pointer value to store in the window words.

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinSetWindowPtr - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

PMERR_PARAMETER_OUT_OF_RANGE (0x1003)
The value of a parameter was not within the defined valid range for that parameter.

WinSetWindowPtr - Example Code

This function retrieves a pointer value from the memory of the reserved window word.

```
MyWindowProc(HWND hwnd, ULONG msg, MPARAM mp1, MPARAM mp2)
{
    MYINSTANCEDATA *InstanceData; /* application defined structure */

    switch (msg) {
    case WM_CREATE:
        DosAllocMem(&InstanceData, sizeof(MYINSTANCEDATA), fALLOC);
        /* WindowProcedure initializes instance data for this window */
        .
        .
        /* set pointer to instance in window words */
        WinSetWindowPtr(hwnd, 0, InstanceData);
        break;

    case WM_USER + 1: /* application defined message */
        /* Window procedure retrieves instance data to */
        /* process this message */
        InstanceData = WinQueryWindowPtr(hwnd, 0);
        .
        .
        break;
    .
    .
    }
```

WinSetWindowText

WinSetWindowText - Syntax

This function sets the window text for a specified window.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */  
#include <os2.h>  
  
HWND    hwnd;          /* Window handle. */  
PSZ     pszString;     /* Window text. */  
BOOL    rc;            /* Success indicator. */  
  
rc = WinSetWindowText(hwnd, pszString);
```

WinSetWindowText Parameter - hwnd

hwnd ([HWND](#)) - input
Window handle.

WinSetWindowText Parameter - pszString

pszString ([PSZ](#)) - input
Window text.

WinSetWindowText Return Value - rc

rc ([BOOL](#)) - returns

Success indicator.

TRUE

Text updated

FALSE

Error occurred.

WinSetWindowText - Parameters

hwnd ([HWND](#)) - input
Window handle.

pszString ([PSZ](#)) - input
Window text.

rc ([BOOL](#)) - returns
Success indicator.

TRUE

Text updated

FALSE

Error occurred.

WinSetWindowText - Remarks

This function sends a [WM_SETWINDOWPARAMS](#) message to the window identified by *hwnd*.

If this function references the window of another process, *pszString* must be in memory that is shared by both processes; otherwise, a memory error may occur.

If *hwnd* has a style of `WS_FRAME`, the title-bar window text is set.

Some window classes interpret the *pszString* in a special way. The tilde character (~) indicates that the following character is a mnemonic; for details, see

WinSetWindowText - Errors

Possible returns from [WinGetLastError](#)

`PMERR_INVALID_HWND (0x1001)`
An invalid window handle was specified.

WinSetWindowThunkProc

WinSetWindowThunkProc - Syntax

This function associates a pointer-conversion procedure with a window.

```
#define INCL_WINTHUNKAPI /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwnd;          /* Window handle. */
PFN     pthunkpr;       /* Pointer-conversion procedure identifier. */
BOOL     rc;            /* Success indicator. */

rc = WinSetWindowThunkProc(hwnd, pthunkpr);
```

WinSetWindowThunkProc Parameter - hwnd

hwnd (**HWND**) - input
Window handle.

WinSetWindowThunkProc Parameter - pthunkpr

pthunkpr (**PFN**) - input
Pointer-conversion procedure identifier.

NULL	Any existing pointer-conversion procedure is dissociated from this window.
Other	The pointer-conversion procedure to be associated with this window.

WinSetWindowThunkProc Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	An error occurred.

WinSetWindowThunkProc - Parameters

hwnd (HWND)	- input
Window handle.	
pthunkpr (PFN)	- input
Pointer-conversion procedure identifier.	
NULL	Any existing pointer-conversion procedure is dissociated from this window.
Other	The pointer-conversion procedure to be associated with this window.
rc (BOOL)	- returns
Success indicator.	
TRUE	Successful completion
FALSE	An error occurred.

WinSetWindowULong

WinSetWindowULong - Syntax

This function sets an unsigned, long integer value into the memory of the reserved window words.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwnd;    /* Window handle. */
LONG    index;   /* Zero-based index of the value to be set. */
ULONG    ul;     /* Unsigned, long integer value to store in the window words. */
BOOL    rc;      /* Success indicator. */

rc = WinSetWindowULong(hwnd, index, ul);
```

WinSetWindowULong Parameter - hwnd

hwnd ([HWND](#)) - input
Window handle.

WinSetWindowULong Parameter - index

index ([LONG](#)) - input
Zero-based index of the value to be set.

The units of *index* are bytes. Valid values are zero through (*cbWindowData* -4), where *cbWindowData* is the parameter in [WinRegisterClass](#) that specifies the number of bytes available for application-defined storage. Any of the QWL_* values are also valid.

Note: QWS_* values cannot be used.

QWL_DEFBUTTON

The default push button for a dialog.

The default push button is the one that sends its [WM_COMMAND](#) message when the enter key is pressed.

QWL_HMQ

Handle of message queue of window. Note that the leading 16 bits of this value are zero.

QWL_HWNDFOCUSSAVE	Window handle of the child windows of this window that last possessed the focus when this frame window was last deactivated.
QWL_PENDATA	Reserved for use by operating system extensions. It allows an operating system extension to store data on a per window basis.
QWL_STYLE	Window style.
QWL_USER	<p>A ULONG value for applications to use is present at offset QWL_USER in windows of the following preregistered window classes:</p> <div> WC_BUTTON WC_COMBOBOX WC_CONTAINER WC_ENTRYFIELD WC_FRAME (includes dialog windows) WC_LISTBOX WC_MENU WC_MLE WC_NOTEBOOK WC_SCROLLBAR WC_SLIDER WC_SPINBUTTON WC_STATIC WC_TITTLEBAR WC_VALUESET </div> <p>This value can be used to place application-specific data in controls.</p>
Other	Zero-based index.

WinSetWindowULONG Parameter - ul

ul (**ULONG**) - input
 Unsigned, long integer value to store in the window words.

WinSetWindowULONG Return Value - rc

rc (**BOOL**) - returns
 Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinSetWindowULONG - Parameters

hwnd (**HWND**) - input
Window handle.

index (**LONG**) - input
Zero-based index of the value to be set.

The units of *index* are bytes. Valid values are zero through (*cbWindowData* -4), where *cbWindowData* is the parameter in [WinRegisterClass](#) that specifies the number of bytes available for application-defined storage. Any of the QWL_* values are also valid.

Note: QWS_* values cannot be used.

QWL_DEFBUTTON	The default push button for a dialog. The default push button is the one that sends its WM_COMMAND message when the enter key is pressed.
QWL_HMQ	Handle of message queue of window. Note that the leading 16 bits of this value are zero.
QWL_HWNDFOCUSSAVE	Window handle of the child windows of this window that last possessed the focus when this frame window was last deactivated.
QWL_PENDATA	Reserved for use by operating system extensions. It allows an operating system extension to store data on a per window basis.
QWL_STYLE	Window style.
QWL_USER	A ULONG value for applications to use is present at offset QWL_USER in windows of the following preregistered window classes: WC_BUTTON WC_COMBOBOX WC_CONTAINER WC_ENTRYFIELD WC_FRAME (includes dialog windows) WC_LISTBOX WC_MENU WC_MLE WC_NOTEBOOK WC_SCROLLBAR WC_SLIDER WC_SPINBUTTON WC_STATIC WC_TITTLEBAR WC_VALUESET This value can be used to place application-specific data in controls.
Other	Zero-based index.

ul (**ULONG**) - input
Unsigned, long integer value to store in the window words.

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinSetWindowULong - Remarks

The specified *index* is valid only if all of the bytes referenced are within the reserved memory.

WinSetWindowULong - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

PMERR_PARAMETER_OUT_OF_RANGE (0x1003)

WinSetWindowULong - Example Code

This example transfers a pointer from the application-defined data area of a dialog window to the application-defined data area (window word) of a main window. The pointer is then retrieved.

```
#define INCL_WINWINDOWMGR
#include <OS2.H>

HWND hwndClient;
ULONG msg;
MPARAM pParm, mp1, mp2;

/* Inside dialog procedure */
switch( msg )
{
    case WM_INITDLG:
        /* This points to the data area and is passed by */
        /* WinLoadDlg, WinCreateDlg, and WinDlgBox */
        /* in their pCreateParams parameter. */
        pParm = (MPARAM)mp2;

        /* Place the pointer in the window word area */
        WinSetWindowULong(hwndClient,
                          QWL_USER,
                          (ULONG) pParm);

    case WM_COMMAND:
        switch (SHORT1FROMMP(mp1))
        {
            case DID_OK:
                /* Retrieve the pointer from the window word area */
```

```
        pParm = (MPARAM)WinQueryWindowULong(hwndClient,
                                              QWL_USER);
    }
}
```

WinSetWindowUShort

WinSetWindowUShort - Syntax

This function sets an unsigned, short integer value into the memory of the reserved window words.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwnd; /* Window handle. */
LONG      index; /* Zero-based index of the value to be set. */
USHORT    us; /* Unsigned, short integer value to store in the window words. */
BOOL      rc; /* Success indicator. */

rc = WinSetWindowUShort(hwnd, index, us);
```

WinSetWindowUShort Parameter - hwnd

hwnd ([HWND](#)) - input
Window handle.

WinSetWindowUShort Parameter - index

index ([LONG](#)) - input

Zero-based index of the value to be set.

The units of *index* are bytes. Valid values are zero through (*cbWindowData* -2), where *cbWindowData* is the parameter in [WinRegisterClass](#) that specifies the number of bytes available for application-defined storage. Any of the following QWS_* values are also valid.

Note: QWL_* values cannot be used.

QWS_CXRESTORE

The width to which the window is restored.

See also the QWS_CYRESTORE value.

QWS_CYRESTORE

The height to which the window is restored.

These values are only valid while the window is maximized or minimized (that is, while either the WS_MINIMIZED or WS_MAXIMIZED window style indicators are set). Changing these values with the WinSetWindowUShort call alters the restore size and position.

QWS_FLAGS

These indicators apply only to frame or dialog windows, and contain combinations of the following indicators:

FF_ACTIVE	Frame window is displayed in the active state.
FF_DIALOGBOX	Frame window is being used as a dialog box.
FF_DLGDISMISSED	Dialog has been dismissed by the WinDismissDlg function.
FF_FLASHHILITE	Window is currently flashed. This indicator toggles with each flash.
FF_FLASHWINDOW	Frame window is flashing.
FF_OWNERDISABLED	Window's owner is disabled. This indicator is only set if the window and its owner are siblings.
FF_OWNERHIDDEN	Frame window is hidden as a result of its owner being hidden or minimized. This indicator is set only if the window and its owner are siblings.
FF_SELECTED	Frame window is selected.

QWS_ID

Window identity. The value of the *id* parameter of the [WinCreateWindow](#) function.

QWS_RESULT

Dialog-result parameter, as established by the [WinDismissDlg](#) function.

QWS_XMINIMIZE

The x-coordinate of the position to which the window is minimized. If this value is -1, the window has not been minimized.

See also the QWS_YMINIMIZE value.

QWS_XRESTORE

The x-coordinate of the position to which the window is restored.

See also the QWS_CYRESTORE value.

QWS_YMINIMIZE

The y-coordinate of the position to which the window is minimized.

When the window is minimized for the first time an arbitrary position is chosen. Changing these values with the WinSetWindowUShort call alters the position of the minimized window, but only when the window is not in a minimized state.

QWS_YRESTORE

	The y-coordinate of the position to which the window is restored.
	See also the QWS_CYRESTORE value.
Other	Zero-based index.

WinSetWindowUShort Parameter - us

us ([USHORT](#)) - input
Unsigned, short integer value to store in the window words.

WinSetWindowUShort Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinSetWindowUShort - Parameters

hwnd ([HWND](#)) - input
Window handle.

index ([LONG](#)) - input
Zero-based index of the value to be set.

The units of *index* are bytes. Valid values are zero through (*cbWindowData* -2), where *cbWindowData* is the parameter in [WinRegisterClass](#) that specifies the number of bytes available for application-defined storage. Any of the following QWS_* values are also valid.

Note: QWL_* values cannot be used.

QWS_CXRESTORE
The width to which the window is restored.
See also the QWS_CYRESTORE value.

QWS_CYRESTORE
The height to which the window is restored.

These values are only valid while the window is maximized or minimized (that is, while either the WS_MINIMIZED or WS_MAXIMIZED window style indicators are set). Changing these values with the WinSetWindowUShort call alters the restore size and position.

QWS_FLAGS
These indicators apply only to frame or dialog windows, and contain combinations of the following indicators:

	FF_ACTIVE	Frame window is displayed in the active state.
	FF_DIALOGBOX	Frame window is being used as a dialog box.
	FF_DLGDISMISSED	Dialog has been dismissed by the WinDismissDlg function.
	FF_FLASHHILITE	Window is currently flashed. This indicator toggles with each flash.
	FF_FLASHWINDOW	Frame window is flashing.
	FF_OWNERDISABLED	Window's owner is disabled. This indicator is only set if the window and its owner are siblings.
	FF_OWNERHIDDEN	Frame window is hidden as a result of its owner being hidden or minimized. This indicator is set only if the window and its owner are siblings.
	FF_SELECTED	Frame window is selected.
QWS_ID	Window identity. The value of the <i>id</i> parameter of the WinCreateWindow function.	
QWS_RESULT	Dialog-result parameter, as established by the WinDismissDlg function.	
QWS_XMINIMIZE	The x-coordinate of the position to which the window is minimized. If this value is -1, the window has not been minimized. See also the QWS_YMINIMIZE value.	
QWS_XRESTORE	The x-coordinate of the position to which the window is restored. See also the QWS_CYRESTORE value.	
QWS_YMINIMIZE	The y-coordinate of the position to which the window is minimized. When the window is minimized for the first time an arbitrary position is chosen. Changing these values with the WinSetWindowUShort call alters the position of the minimized window, but only when the window is not in a minimized state.	
QWS_YRESTORE	The y-coordinate of the position to which the window is restored. See also the QWS_CYRESTORE value.	
Other	Zero-based index.	
us (USHORT) - input	Unsigned, short integer value to store in the window words.	
rc (BOOL) - returns	Success indicator.	
TRUE	Successful completion	
FALSE	Error occurred.

WinShowCursor

WinShowCursor - Syntax

This function shows or hides the cursor that is associated with a specified window.

```
#define INCL_WINCursors /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HWND    hwnd; /* Handle of window to which the cursor belongs. */
BOOL    fShow; /* Show indicator. */
BOOL    rc; /* Success indicator. */
```

```
rc = WinShowCursor(hwnd, fShow);
```

WinShowCursor Parameter - hwnd

hwnd (**HWND**) - input
Handle of window to which the cursor belongs.

WinShowCursor Parameter - fShow

fShow (**BOOL**) - input
Show indicator.

TRUE	Make cursor visible
FALSE	Make cursor invisible.

WinShowCursor Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred, or an attempt was made to show the cursor when it was already visible.

WinShowCursor - Parameters

hwnd (**HWND**) - input
Handle of window to which the cursor belongs.

fShow (**BOOL**) - input
Show indicator.

TRUE	Make cursor visible
FALSE	Make cursor invisible.

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred, or an attempt was made to show the cursor when it was already visible.

WinShowCursor - Remarks

This function must be called by the same thread that created the cursor that is affected.

A cursor show-level count is maintained. It is incremented by a hide operation and decremented by a show operation. The cursor is actually visible if the cursor show-level count is zero, otherwise it is invisible. When decrementing, the cursor show-level count is fixed at zero so as not to show the cursor too many times, but it is possible to hide the cursor a number of times in succession.

WinShowCursor - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinShowCursor - Example Code

This example shows the cursor if it is successfully created.

```
#define INCL_WINCursors
#include <OS2.H>

HWND hwnd; /* handle of window that has pointer captured */
RECT rcl;

WinQueryWindowRect(hwnd, &rcl);

if (WinCreateCursor(hwnd, /* This must be the handle */
                    /* of a window for which */
                    /* the application can */
                    /* receive input. */
                    100, /* x,y position of cursor. */
                    100,
                    5, /* cursor width. */
                    5, /* cursor height. */) != 0)
```

```

        CURSOR_FLASH,
        &rc1)) /* region where the cursor */
                /* is visible. */
WinShowCursor(hwnd,
                TRUE); /* make cursor visible. */

```

WinShowPointer

WinShowPointer - Syntax

This function adjusts the pointer display level to show or hide a pointer.

```

#define INCL_WINPOINTERS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwndDesktop; /* Desktop-window handle. */
BOOL    fShow;        /* Level-update indicator. */
BOOL    rc;           /* Display-level-updated indicator. */

rc = WinShowPointer(hwndDesktop, fShow);

```

WinShowPointer Parameter - hwndDesktop

hwndDesktop (HWND) - input
Desktop-window handle.

HWND_DESKTOP
 The desktop-window handle

Other
 The specified desktop-window handle.

WinShowPointer Parameter - fShow

fShow (BOOL) - input	Level-update indicator.
TRUE	Decrement pointer display level by one. (The pointer level is not decremented to a negative value.)
FALSE	Increment pointer display level by one.

WinShowPointer Return Value - rc

rc (BOOL) - returns	Display-level-updated indicator.
TRUE	Pointer display level successfully updated.
FALSE	Pointer display level not successfully updated

WinShowPointer - Parameters

hwndDesktop (HWND) - input	Desktop-window handle.
HWND_DESKTOP	The desktop-window handle
Other	The specified desktop-window handle.
fShow (BOOL) - input	Level-update indicator.
TRUE	Decrement pointer display level by one. (The pointer level is not decremented to a negative value.)
FALSE	Increment pointer display level by one.
rc (BOOL) - returns	Display-level-updated indicator.
TRUE	Pointer display level successfully updated.
FALSE	Pointer display level not successfully updated

WinShowPointer - Remarks

The pointer display level determines whether the pointer is shown. If it is zero, the pointer is visible, but if it is greater than zero, the pointer is not visible. The initial setting of the pointer display level is dependent on the capabilities of the device. If a pointing device exists, the initial setting of the pointer display level is zero, otherwise it is one. The existing pointer display level can be obtained by using the [WinQuerySysValue](#) function with *iSysValue* set to SV_POINTERLEVEL.

WinShowPointer - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinShowTrackRect

WinShowTrackRect - Syntax

This function hides or shows the tracking rectangle.

```
#define INCL_WINTRACKRECT /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwnd;    /* Window handle. */
BOOL    fShow;   /* Show indicator. */
BOOL    rc;      /* Success indicator. */

rc = WinShowTrackRect(hwnd, fShow);
```

WinShowTrackRect Parameter - hwnd

hwnd ([HWND](#)) - input
Window handle.

Passed to the [WinTrackRect](#) function.

WinShowTrackRect Parameter - fShow

fShow ([BOOL](#)) - input
Show indicator.

TRUE	Show the tracking rectangle
FALSE	Hide the tracking rectangle.

WinShowTrackRect Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinShowTrackRect - Parameters

hwnd (**HWND**) - input
Window handle.

Passed to the [WinTrackRect](#) function.

fShow (**BOOL**) - input
Show indicator.

TRUE	Show the tracking rectangle
FALSE	Hide the tracking rectangle.

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinShowTrackRect - Remarks

This function maintains a show count. When a hide request is made, this count is decremented; when a show request is made, the count is incremented. When the count makes a transition from 0 to -1, the rectangle is hidden; when the count makes a transition from -1 to 0, the rectangle is shown.

When a rectangle is tracking, the application must call this function to hide the rectangle if there is a possibility of corrupting the tracking rectangle while drawing. The rectangle is shown afterwards. Because the structure is updated continuously, the application can examine the coordinates of the current tracking rectangle to determine whether temporary hiding is necessary.

The only case where an application needs to use this function is during asynchronous drawing. If an application is drawing on one thread, and issuing [WinTrackRect](#) on another, unwanted areas of tracking rectangle may be left behind. The drawing thread is therefore responsible for calling this function whenever tracking is in progress. The application must provide for communication between the two threads to ensure that if one thread is tracking, the drawing thread issues this function. This can be done with a *semaphore*.

WinShowTrackRect - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinShowWindow

WinShowWindow - Syntax

This function sets the visibility state of a window.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HWND     hwnd;           /* Window handle. */
BOOL     fNewVisibility; /* New visibility state. */
BOOL     rc;             /* Visibility changed indicator. */

rc = WinShowWindow(hwnd, fNewVisibility);
```

WinShowWindow Parameter - hwnd

hwnd (**HWND**) - input
Window handle.

WinShowWindow Parameter - fNewVisibility

fNewVisibility (**BOOL**) - input
New visibility state.

- TRUE Set window state visible
- FALSE Set window state invisible.

WinShowWindow Return Value - rc

rc (**BOOL**) - returns
Visibility changed indicator.

- TRUE Window visibility successfully changed
- FALSE Window visibility not successfully changed.

WinShowWindow - Parameters

hwnd (**HWND**) - input
Window handle.

fNewVisibility (**BOOL**) - input
New visibility state.

- TRUE Set window state visible
- FALSE Set window state invisible.

rc (**BOOL**) - returns
Visibility changed indicator.

- TRUE Window visibility successfully changed
- FALSE Window visibility not successfully changed.

WinShowWindow - Remarks

A window possesses a visibility state indicated by the WS_VISIBLE style bit. When the WS_VISIBLE style bit is set, the window is shown and subsequent drawing into the window is presented, unless that window is obscured by some other window, or at least one of the windows upward in the parent chain from *hwnd* does not have the WS_VISIBLE style.

When the WS_VISIBLE style bit is not set, the window is not shown ("hidden") and subsequent drawing into the window is not presented, even if that window is not obscured by another window.

If the value of the WS_VISIBLE style bit has been changed, the [WM_SHOW](#) message is sent to the window of *hwnd* before the function returns.

WinShowWindow - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinShutdownSystem

WinShutdownSystem - Syntax

The WinShutdownSystem function will close down the system.

```
#define INCL_WINWORKPLACE
#include <os2.h>
```

```
HAB    hab; /* Anchor-block handle. */
HMQ    hmq; /* Message-queue handle. */
BOOL    rc; /* Success indicator. */

rc = WinShutdownSystem(hab, hmq);
```

WinShutdownSystem Parameter - hab

hab (**HAB**) - input
Anchor-block handle.

WinShutdownSystem Parameter - hmq

hmq (**HMQ**) - input
Message-queue handle.

WinShutdownSystem Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinShutdownSystem - Parameters

hab (**HAB**) - input
Anchor-block handle.

hmq (**HMQ**) - input
Message-queue handle.

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinShutdownSystem - Remarks

The WinShutdownSystem function will close all running applications and will then call DosShutdown.

Presentation Manager applications will receive a WM_SAVEAPPLICATION message prior to a WM_QUIT message.

When the system is restarted, all applications that were running when WinShutdownSystem was last called will be restarted.

WinStartApp

WinStartApp - Syntax

This function starts an application.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwndNotify; /* Notification-window handle. */
PPROGDETAILS pDetails; /* Program list structure. */
PSZ        pszParams; /* Input parameters for the application to be started. */
PVOID      pReserved; /* Start data. */
ULONG      ulOptions; /* Option indicators. */
HAPP       happ; /* Application handle. */

happ = WinStartApp(hwndNotify, pDetails, pszParams,
                  pReserved, ulOptions);
```

WinStartApp Parameter - hwndNotify

hwndNotify ([HWND](#)) - input
Notification-window handle.

A [WM_APPTERMINATENOTIFY](#) message is posted to this window, when the started application terminates.

WinStartApp Parameter - pDetails

pDetails ([PPROGDETAILS](#)) - input
Program list structure.

WinStartApp Parameter - pszParams

pszParams ([PSZ](#)) - input
Input parameters for the application to be started.

This specifies the command line parameters to be passed to this application when it starts.

WinStartApp Parameter - pReserved

pReserved ([PVOID](#)) - input
Start data.

Reserved, must be NULL.

WinStartApp Parameter - ulOptions

ulOptions ([ULONG](#)) - input
Option indicators.

If more than one option is selected, the values can be ORed together.

WinStartApp Return Value - happ

happ ([HAPP](#)) - returns
Application handle.

NULL	Application not started.
Other	Application handle.

WinStartApp - Parameters

hwndNotify ([HWND](#)) - input
Notification-window handle.

A [WM_APPTERMINATENOTIFY](#) message is posted to this window, when the started application terminates.

pDetails ([PPROGDETAILS](#)) - input

Program list structure.

pszParams ([PSZ](#)) - input

Input parameters for the application to be started.

This specifies the command line parameters to be passed to this application when it starts.

pReserved ([PVOID](#)) - input

Start data.

Reserved, must be NULL.

ulOptions ([ULONG](#)) - input

Option indicators.

If more than one option is selected, the values can be ORed together.

happ ([HAPP](#)) - returns

Application handle.

NULL

Application not started.

Other

Application handle.

WinStartApp - Remarks

Starts the application identified in [PROGDETAILS](#). If the `ulOptions` parameter has the `SAF_INSTALLED_CMDLINE` set, the `pszParameters` in the `PROGDETAILS` structure is used; otherwise the `pszParams` passed in this function is used.

If the application is successfully started, the return value is a handle to the application. If `SAF_STARTCHILDAPP` is specified, this can be used to stop the application (see [WinTerminateApp](#)).

When the program specified by the application handle terminates, the window specified by the *hwndNotify* parameter (if the window still exists and is valid) has a [WM_APP_TERMINATENOTIFY](#) message posted to it to notify it of the application termination.

This function requires the existence of a message queue.

If Dos/Windows applications have to be started with `WinStartApp`, Global settings from the `USERPROFILE` will have to be read and passed in the [PROGDETAILS](#) structure in the *pszEnvironment* variable. If not done, `WinStartApp` will take the system default values and start the application.

WinStartApp - Errors

Possible returns from [WinGetLastError](#)

`PMERR_DOS_ERROR` (0x1200)

A DOS call returned an error.

`PMERR_INVALID_APPL` (0x1530)

Attempted to start an application whose type is not recognized by OS/2.

`PMERR_INVALID_PARAMETERS` (0x1208)

An application parameter value is invalid for its converted PM type. For example: a 4-byte value outside the range -32 768 to +32 767 cannot be converted to a [SHORT](#), and a negative number cannot be converted to a [ULONG](#) or [USHORT](#).

`PMERR_INVALID_WINDOW` (0x1206)

The window specified with a Window List call is not a valid frame window.

`PMERR_STARTED_IN_BACKGROUND` (0x1532)

The application started a new session in the background.

WinStartTimer

WinStartTimer - Syntax

This function starts a timer.

```
#define INCL_WINTIMER /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;           /* Anchor-block handle. */
HWND     hwnd;          /* Window handle that is part of the timer identification. */
ULONG     idTimer;       /* Timer identifier. */
ULONG     dtTimeout;     /* Delay time in milliseconds. */
ULONG     idTimerStarted; /* Timer identity. */

idTimerStarted = WinStartTimer(hab, hwnd,
                               idTimer, dtTimeout);
```

WinStartTimer Parameter - hab

hab (**HAB**) - input
Anchor-block handle.

WinStartTimer Parameter - hwnd

hwnd (**HWND**) - input
Window handle that is part of the timer identification.

NULLHANDLE

The *idTimer* parameter is ignored, and this function returns a unique, nonzero, identity which represents that timer. The timer message is posted in the queue associated with the current thread, with the parameter of the **QMSG** structure set to NULLHANDLE.

Other

Window handle.

WinStartTimer Parameter - idTimer

idTimer (**ULONG**) - input
Timer identifier.

The value of an application-timer identifier must be below TID_USERMAX to avoid clashes with timers used by the system.

A timer identification, TID_SCROLL, is created by a scroll bar control. An application does not normally see the associated WM_TIMER, but passes it to the scroll-bar control.

A timer identification, TID_CURSOR, is created when the cursor is flashing. An application must ensure that the associated WM_TIMER is passed on to the default window procedure.

WinStartTimer Parameter - dtTimeout

dtTimeout (ULONG) - input
Delay time in milliseconds.

For OS/2 Warp Version 3, the value of this parameter must be in the range of 0-4 294 967 295.

For OS/2 2.1 and earlier, the value of this parameter must be in the range of 0-65 535.

WinStartTimer Return Value - idTimerStarted

idTimerStarted (ULONG) - returns
Timer identity.

A return value of 0 indicates that an error occurred.

WinStartTimer - Parameters

hab (HAB) - input
Anchor-block handle.

hwnd (HWND) - input
Window handle that is part of the timer identification.

NULLHANDLE

The *idTimer* parameter is ignored, and this function returns a unique, nonzero, identity which represents that timer. The timer message is posted in the queue associated with the current thread, with the parameter of the QMSG structure set to NULLHANDLE.

Other

Window handle.

idTimer (ULONG) - input
Timer identifier.

The value of an application-timer identifier must be below TID_USERMAX to avoid clashes with timers used by the system.

A timer identification, TID_SCROLL, is created by a scroll bar control. An application does not normally see the associated WM_TIMER, but passes it to the scroll-bar control.

A timer identification, TID_CURSOR, is created when the cursor is flashing. An application must ensure that the associated WM_TIMER is passed on to the default window procedure.

dtTimeout (ULONG) - input
Delay time in milliseconds.

For OS/2 Warp Version 3, the value of this parameter must be in the range of 0-4 294 967 295.

For OS/2 2.1 and earlier, the value of this parameter must be in the range of 0-65 535.

idTimerStarted ([ULONG](#)) - returns
Timer identity.

A return value of 0 indicates that an error occurred.

WinStartTimer - Remarks

This function creates a timer identified by *hwnd* and *idTimer*, set to time out every *dtTimeout* milliseconds. When a timer times out, a [WM_TIMER](#) message is posted.

A *dtTimeout* value of zero causes the timer to timeout as fast as possible; generally, this is about 1/18 second.

A second call to this function, for a timer that already exists, resets that timer.

WinStartTimer - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinStartTimer - Example Code

This example uses the WinStartTimer call to add up elapsed seconds.

```
#define INCL_WINTIMER
#include <OS2.H>

HAB hab; /* Anchor-block handle */
ULONG seconds;
ULONG msg;

WinStartTimer(hab,
              (HWND)0,
              0, /* Ignored as previous parm. is null */
              1000UL);

switch(msg)
{
    case WM_TIMER:
        seconds += 1;
        break;
}
```

WinStopTimer

WinStopTimer - Syntax

This function stops a timer.

```
#define INCL_WINTIMER /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB hab; /* Anchor-block handle. */
HWND hwnd; /* Window handle. */
ULONG ulTimer; /* Timer identifier. */
BOOL rc; /* Success indicator. */

rc = WinStopTimer(hab, hwnd, ulTimer);
```

WinStopTimer Parameter - hab

hab (**HAB**) - input
Anchor-block handle.

WinStopTimer Parameter - hwnd

hwnd (**HWND**) - input
Window handle.

WinStopTimer Parameter - ulTimer

ulTimer (**ULONG**) - input
Timer identifier.

WinStopTimer Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred, or timer did not exist.

WinStopTimer - Parameters

hab (**HAB**) - input
Anchor-block handle.

hwnd (**HWND**) - input
Window handle.

ulTimer (**ULONG**) - input
Timer identifier.

rc (**BOOL**) - returns

Success indicator.

TRUE

Successful completion

FALSE

Error occurred, or timer did not exist.

WinStopTimer - Remarks

When this function is called, no further messages are received from the stopped timer, even if it has timed out since the last call to [WinGetMsg](#).

WinStopTimer - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinStopTimer - Example Code

This example uses the WinStopTimer call to stop a clock after one minute.

```
#define INCL_WINTIMER
#include <OS2.H>
HAB hab;                /* anchor-block handle. */
ULONG ulTimerId;
HWND hwnd;
ulTimerId = WinStartTimer(hab,
                          (HWND)0,
                          0, /* ignored because previous parameter */
                          /* is null. */                          /*
                          1000UL);

BOOL WndProc(. . . . ) {
static ULONG seconds;

switch(msg)
{
case WM_TIMER:
if (seconds) {
```

```

        seconds ++ ;
        if (seconds == 60) WinStopTimer(hab, hwnd, ulTimerId);
    }
    break;
case WM_CREATE:
    seconds = 0;
    .
    .
    .
}

WinStoreWindowPos

WinStoreWindowPos - Syntax

The WinStoreWindowPos function will save the current size and position of the window specified by *hwnd*.

```

#define INCL_WINWORKPLACE
#include <os2.h>

PSZ      pAppName; /* Pointer to application name. */
PSZ      pKeyName; /* Pointer to key name. */
HWND     hwnd;     /* Window handle for the window to be stored. */
BOOL     rc;       /* Success indicator. */

rc = WinStoreWindowPos(pAppName, pKeyName,
    hwnd);

```

WinStoreWindowPos Parameter - pAppName

pAppName ([PSZ](#)) - input

Pointer to application name.

A pointer to a zero-terminated string which contains the application name.

WinStoreWindowPos Parameter - pKeyName

pKeyName (PSZ) - input

Pointer to key name.

A pointer to a zero-terminated string which contains the key name.

WinStoreWindowPos Parameter - hwnd

hwnd (HWND) - input

Window handle for the window to be stored.

WinStoreWindowPos Return Value - rc

rc (BOOL) - returns

Success indicator.

TRUE

Successful completion

FALSE

Error occurred.

WinStoreWindowPos - Parameters

pAppName (PSZ) - input

Pointer to application name.

A pointer to a zero-terminated string which contains the application name.

pKeyName (PSZ) - input

Pointer to key name.

A pointer to a zero-terminated string which contains the key name.

hwnd (HWND) - input

Window handle for the window to be stored.

rc (BOOL) - returns

Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinStoreWindowPos - Remarks

This function will also save the presentation parameters.

WinStretchPointer

WinStretchPointer - Syntax

This function draws a pointer in the passed *hps* at the passed coordinates [*lx*, *ly*] and at the passed size [*lcx*, *lcy*].

```
#define INCL_WINPOINTERS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HPS      hps;          /* Presentation space handle into which the pointer is drawn. */
LONG     lx;           /* X coordinate at which to draw the pointer, in device coordinates. */
LONG     ly;           /* Y coordinate at which to draw the pointer, in device coordinates. */
LONG     lcx;          /* X size at which to draw the pointer, in device coordinates. */
LONG     lcy;          /* Y size at which to draw the pointer, in device coordinates. */
HPOINTER hptrPointer;  /* Pointer handle. */
ULONG    ulHalftone;   /* Shading control with which to draw the pointer: */
```

```
BOOL          fSuccess;          /* Success indicator: */  
  
fSuccess = WinStretchPointer(hps, lx, ly,  
                             lcx, lcy, hptrPointer, ulHalftone);
```

WinStretchPointer Parameter - hps

hps (**HPS**) - input

Presentation space handle into which the pointer is drawn.

This can be either a micro presentation space or a normal presentation space (see GpiCreatePS).

WinStretchPointer Parameter - lx

lx (**LONG**) - input

X coordinate at which to draw the pointer, in device coordinates.

WinStretchPointer Parameter - ly

ly (**LONG**) - input

Y coordinate at which to draw the pointer, in device coordinates.

WinStretchPointer Parameter - lcx

lcx (**LONG**) - input

X size at which to draw the pointer, in device coordinates.

WinStretchPointer Parameter - lcy

lcy (**LONG**) - input

Y size at which to draw the pointer, in device coordinates.

WinStretchPointer Parameter - hptrPointer

hptrPointer ([HPOINTER](#)) - input
Pointer handle.

The pointer should be loaded using [WinLoadPointer](#), [WinCreatePointer](#), or [WinCreatePointerIndirect](#).

WinStretchPointer Parameter - ulHalftone

ulHalftone ([ULONG](#)) - input
Shading control with which to draw the pointer:

DP_NORMAL	As it normally appears.
DP_HALFTONED	With a halftone pattern where black normally appears.
DP_INVERTED	Inverted-black for white, and white for black.

WinStretchPointer Return Value - fSuccess

fSuccess ([BOOL](#)) - returns
Success indicator:

TRUE	Successful completion.
FALSE	The function failed.

WinStretchPointer - Parameters

hps ([HPS](#)) - input
Presentation space handle into which the pointer is drawn.

This can be either a micro presentation space or a normal presentation space (see [GpiCreatePS](#)).

lx ([LONG](#)) - input
X coordinate at which to draw the pointer, in device coordinates.

ly ([LONG](#)) - input
Y coordinate at which to draw the pointer, in device coordinates.

lcx ([LONG](#)) - input
X size at which to draw the pointer, in device coordinates.

lcy ([LONG](#)) - input
Y size at which to draw the pointer, in device coordinates.

hptrPointer ([HPOINTER](#)) - input
Pointer handle.

The pointer should be loaded using [WinLoadPointer](#), [WinCreatePointer](#), or [WinCreatePointerIndirect](#).

ulHalftone ([ULONG](#)) - input

Shading control with which to draw the pointer:

DP_NORMAL	As it normally appears.
DP_HALFTONED	With a halftone pattern where black normally appears.
DP_INVERTED	Inverted-black for white, and white for black.

fSuccess ([BOOL](#)) - returns

Success indicator:

TRUE	Successful completion.
FALSE	The function failed.

WinStretchPointer - Remarks

This function should only be used in draw mode (DM_DRAW) to a screen device context.

The function checks the supplied pointer to determine whether it contains a pointer format matching the size passed. If there is no such match the default format is stretched to size.

WinStretchPointer - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HPTR (0x101B)
An invalid pointer handle was specified.

PMERR_INVALID_FLAG (0x1019)
An invalid bit was set for a parameter. Use constants defined by PM for options, and do not set any reserved bits.

WinSubclassWindow

WinSubclassWindow - Syntax

This function subclasses the indicated window by replacing its window procedure with another window procedure, specified by *pNewWindowProc*.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwnd;          /* Handle of window that is being subclassed. */
PFNWP     pNewWindowProc; /* New window procedure. */
PFNWP     pOldWindowProc; /* Old window procedure. */

pOldWindowProc = WinSubclassWindow(hwnd, pNewWindowProc);
```

WinSubclassWindow Parameter - hwnd

hwnd (**HWND**) - input
Handle of window that is being subclassed.

WinSubclassWindow Parameter - pNewWindowProc

pNewWindowProc (**PFNWP**) - input
New window procedure.

Window procedure used to subclass *hwnd*.

WinSubclassWindow Return Value - pOldWindowProc

pOldWindowProc (**PFNWP**) - returns
Old window procedure.

Previous window procedure belonging to *hwnd*.

If this function fails, 0L is returned.

WinSubclassWindow - Parameters

hwnd (**HWND**) - input
Handle of window that is being subclassed.

pNewWindowProc (**PFNWP**) - input
New window procedure.

Window procedure used to subclass *hwnd*.

pOldWindowProc (**PFNWP**) - returns
Old window procedure.

Previous window procedure belonging to *hwnd*.

If this function fails, 0L is returned.

WinSubclassWindow - Remarks

To subclass a window effectively, the new window procedure calls the old window procedure rather than [WinDefWindowProc](#), for those messages it does not process itself.

To reverse the effect of subclassing, call this function again using the old window procedure address.

Note: It is not possible to subclass a window created by another process.

WinSubclassWindow - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinSubclassWindow - Example Code

This example uses the WinSubclassWindow call to subclass the frame window procedure, so that frame-sizing restrictions can be implemented.

```
#define INCL_WINWINDOWMGR
#include <OS2.H>
HAB hab;
PFNWP FrameWndProc, OldpFrame;
HWND hwndFrame;
```

```
OldpFrame = WinSubclassWindow(hwndFrame,  
                                (PFNWP)FrameWndProc);
```

```
MRESULT EXPENTRY FrameWndProc(hwnd, msg, mp1, mp2)  
{  
    .  
    .  
    .  
    switch(msg) {  
        case . . . :  
            .  
            .  
            .  
        default:  
            OldpFrame(hwnd, msg, mp1, mp2);  
    }  
}
```

WinSubstituteStrings

WinSubstituteStrings - Syntax

This function performs a substitution process on a text string, replacing specific marker characters with text supplied by the application.

```
#define INCL_WINDIALOGS /* Or use INCL_WIN, INCL_PM, */  
#include <os2.h>  
  
HWND    hwnd;        /* Handle of window that processes the call. */  
PSZ     pszSrc;       /* Source string. */  
LONG    lDestMax;     /* Maximum number of characters returnable. */  
PSZ     pszDest;      /* Resultant string. */  
LONG    lDestRet;     /* Actual number of characters returned. */  
  
lDestRet = WinSubstituteStrings(hwnd, pszSrc,  
                                lDestMax, pszDest);
```

WinSubstituteStrings Parameter - hwnd

hwnd ([HWND](#)) - input
Handle of window that processes the call.

WinSubstituteStrings Parameter - pszSrc

pszSrc ([PSZ](#)) - input
Source string.

This is the text string that is to have substitution performed.

WinSubstituteStrings Parameter - IDestMax

IDestMax ([LONG](#)) - input
Maximum number of characters returnable.

This is the maximum number of characters that can be returned in *pszDest*. It must be greater than 0.

WinSubstituteStrings Parameter - pszDest

pszDest ([PSZ](#)) - output
Resultant string.

This is the text string produced by the substitution process.

The string is truncated if it would otherwise contain more than *IDestMax* characters. When truncation occurs, the last character of the truncated string is always the null-termination character.

WinSubstituteStrings Return Value - IDestRet

IDestRet ([LONG](#)) - returns
Actual number of characters returned.

This is the actual number returned in *pszDest*, excluding the null-termination character. The maximum value is (*IDestMax*-1). It is zero if an error occurred.

WinSubstituteStrings - Parameters

hwnd ([HWND](#)) - input
Handle of window that processes the call.

pszSrc ([PSZ](#)) - input
Source string.

This is the text string that is to have substitution performed.

IDestMax ([LONG](#)) - input
Maximum number of characters returnable.

This is the maximum number of characters that can be returned in *pszDest*. It must be greater than 0.

pszDest ([PSZ](#)) - output
Resultant string.

This is the text string produced by the substitution process.

The string is truncated if it would otherwise contain more than *IDestMax* characters. When truncation occurs, the last character of the truncated string is always the null-termination character.

IDestRet ([LONG](#)) - returns
Actual number of characters returned.

This is the actual number returned in *pszDest*, excluding the null-termination character. The maximum value is (*IDestMax*-1). It is zero if an error occurred.

WinSubstituteStrings - Remarks

When a string of the form "%n" (where n is in the range 0 through 9) occurs in the source string, a [WM_SUBSTITUTESTRING](#) message is sent to the specified window. This message returns a text string to use as a substitution for "%n" in the destination string, which is otherwise an exact copy of the source string.

If "%%" occurs in the source, "%" is copied to the destination, but no other substitution occurs. If "%x" occurs in the source, where x is not a digit or "%", the source is copied unchanged to the destination. The source and destination strings must not overlap in memory.

This function is particularly useful for displaying variable information in dialogs, menus, and other user-interface calls. Variable information can include such things as file names, which cannot be statically declared within resource files.

This function is called by the system while creating child windows in a dialog box. It allows the child windows to perform textual substitutions in their window text.

WinSubstituteStrings - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinSubtractRect

WinSubtractRect - Syntax

This function subtracts one rectangle from another.

```
#define INCL_WINRECTANGLES /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
PRECTL   prclDest;     /* Result. */
PRECTL   prclSrc1;     /* First source rectangle. */
PRECTL   prclSrc2;     /* Second source rectangle. */
BOOL      rc;          /* Not-empty indicator. */

rc = WinSubtractRect(hab, prclDest, prclSrc1,
                    prclSrc2);
```

WinSubtractRect Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinSubtractRect Parameter - prclDest

prclDest (**PRECTL**) - output
Result.

The result of the subtraction of *prclSrc2* from *prclSrc1*.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type **WRECT** may also be used, if supported by the language.

WinSubtractRect Parameter - prclSrc1

prclSrc1 (**PRECTL**) - input
First source rectangle.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type **WRECT** may also be used, if supported by the language.

WinSubtractRect Parameter - prclSrc2

prclSrc2 (**PRECTL**) - input
Second source rectangle.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type **WRECT** may also be used, if supported by the language.

WinSubtractRect Return Value - rc

rc (**BOOL**) - returns
Not-empty indicator.

TRUE	Rectangle is not empty
FALSE	Rectangle is empty or an error occurred.

WinSubtractRect - Parameters

hab (**HAB**) - input
Anchor-block handle.

prclDest (**PRECTL**) - output
Result.

The result of the subtraction of *prcSrc2* from *prcSrc1*.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) may also be used, if supported by the language.

prcSrc1 ([PRECTL](#)) - input
First source rectangle.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) may also be used, if supported by the language.

prcSrc2 ([PRECTL](#)) - input
Second source rectangle.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) may also be used, if supported by the language.

rc ([BOOL](#)) - returns
Not-empty indicator.

TRUE	Rectangle is not empty
FALSE	Rectangle is empty or an error occurred.

WinSubtractRect - Remarks

Subtracts *prcSrc2* from *prcSrc1*.

prcSrc1, *prcSrc2*, and *prcDest* must be distinct [RECTL](#) structures.

Subtracting one rectangle from another does not always result in a rectangular area. When this occurs, this function returns *prcSrc1* in *prcDest*. For this reason, this function provides only an approximation of subtraction. However, the area described by *prcDest* is always greater than, or equal to, the true result of the subtraction.

GpiCombineRegion can be used to calculate the true result of the subtraction of two rectangular areas. The WinSubtractRect function is much faster.

WinSubtractRect - Example Code

This example uses the WinSubtractRect call to subtract two rectangles.

```
#define INCL_WINRECTANGLES
#include <OS2.H>
HAB hab;
RECTL resultrcl; /* result. */
RECTL rclminuend={25, /* x coordinate of left-hand edge of */
                  /* rectangle. */
                  25, /* y coordinate of bottom edge of */
                  /* rectangle. */
                  425,/* x coordinate of right-hand edge of */
                  /* rectangle. */
                  425};/* y coordinate of top edge of rectangle. */

RECTL rclsubtrahend={15, /* x coordinate of left-hand edge of */
                    /* rectangle. */
                    15, /* y coordinate of bottom edge of */
                    /* rectangle. */
                    125,/* x coordinate of right-hand edge of */
                    /* rectangle. */
                    125};/* y coordinate of top edge of rectangle.*/

WinSubtractRect(hab,
                &resultrcl,
                &rclminuend,
                &rclsubtrahend);

WinSwitchToProgram

WinSwitchToProgram - Syntax

This function makes a specific program the active program.

```
#define INCL_WINSWITCHLIST /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HSWITCH    hswitchSwHandle; /* Window List entry handle of program to be activated. */
ULONG      rc;              /* Return code. */
```

```
rc = WinSwitchToProgram(hswitchSwHandle);
```

WinSwitchToProgram Parameter - hswitchSwHandle

hswitchSwHandle ([H SWITCH](#)) - input
Window List entry handle of program to be activated.

WinSwitchToProgram Return Value - rc

rc ([ULONG](#)) - returns
Return code.

0
Successful completion.

INV_SWITCH_LIST_ENTRY_HANDLE
Invalid Window List entry handle of the program to be activated.

NOT_PERMITTED_TO_CAUSE_SWITCH
Requesting program is not the current foreground process.

WinSwitchToProgram - Parameters

hswitchSwHandle ([H SWITCH](#)) - input
Window List entry handle of program to be activated.

rc ([ULONG](#)) - returns
Return code.

0
Successful completion.

INV_SWITCH_LIST_ENTRY_HANDLE
Invalid Window List entry handle of the program to be activated.

NOT_PERMITTED_TO_CAUSE_SWITCH
Requesting program is not the current foreground process.

WinSwitchToProgram - Remarks

Use of this function causes another window (and its related windows) of a PM session to appear on the front of the screen, or a switch to another session in the case of a non-PM program. In either case, the keyboard (and mouse for the non-PM case) input is directed to the new program.

WinSwitchToProgram - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_SWITCH_HANDLE (0x1202)
An invalid Window List entry handle was specified.

WinTerminate

WinTerminate - Syntax

This function terminates an application thread's use of the Presentation Manager and releases all of its associated resources.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, Also in COMMON section */
#include <os2.h>

HAB      hab; /* Anchor-block handle. */
BOOL     rc;  /* Termination indicator. */

rc = WinTerminate(hab);
```

WinTerminate Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinTerminate Return Value - rc

rc ([BOOL](#)) - returns
Termination indicator.

TRUE	Application usage of Presentation Manager successfully terminated
FALSE	Application usage of Presentation Manager not successfully terminated, or WinInitialize has not been issued on this thread.

WinTerminate - Parameters

hab ([HAB](#)) - input

Anchor-block handle.

rc ([BOOL](#)) - returns
Termination indicator.

TRUE

Application usage of Presentation Manager successfully terminated

FALSE

Application usage of Presentation Manager not successfully terminated, or [WinInitialize](#) has not been issued on this thread.

WinTerminate - Remarks

It is good practice to issue this function before terminating an application thread. Before issuing this function, the application must destroy all windows and message queues that have been created by the thread, and return any cached presentation spaces to the cache. If it does not do so, the results, and the return value from this and subsequent calls are indeterminate.

WinTerminateApp

WinTerminateApp - Syntax

This function terminates an application previously started with the [WinStartApp](#) function.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAPP    happ; /* Application handle. */
BOOL    rc;    /* Termination indicator. */

rc = WinTerminateApp(happ);
```

WinTerminateApp Parameter - happ

happ ([HAPP](#)) - input
Application handle.

Identifies the application to terminate.

WinTerminateApp Return Value - rc

rc ([BOOL](#)) - returns
Termination indicator.

TRUE

Application successfully terminated
NULL
Error occurred.

WinTerminateApp - Parameters

happ ([HAPP](#)) - input
Application handle.

Identifies the application to terminate.

rc ([BOOL](#)) - returns
Termination indicator.

TRUE	Application successfully terminated
NULL	Error occurred.

WinTerminateApp - Remarks

The application to terminate must have been started using the [WinStartApp](#) function with the SAF_STARTCHILDAPP option specified.

If the specified application does not stop, this function returns TRUE. To ensure that the application has terminated, the application calling WinTerminateApp must wait for the appropriate message to be posted to the window specified in the [WinStartApp](#) function.

The WinTerminateApp function must be called from the same process as the [WinStartApp](#) function.

This function requires the existence of a message queue.

WinTerminateApp - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HAPP (0x1533)
The application handle passed to WinTerminateApp does not correspond to a valid session.

PMERR_CANNOT_STOP (0x1534)
The session cannot be stopped.

WinTrackRect

WinTrackRect - Syntax

This function draws a tracking rectangle.

```
#define INCL_WINTRACKRECT /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwnd;          /* Window handle where tracking is to take place. */
HPS       hps;           /* Presentation-space handle. */
PTRACKINFO ptiTrackinfo; /* Track information. */
BOOL      rc;            /* Success indicator. */

rc = WinTrackRect(hwnd, hps, ptiTrackinfo);
```

WinTrackRect Parameter - hwnd

hwnd (**HWND**) - input

Window handle where tracking is to take place.

It is assumed that the style of this window is not WS_CLIPCHILDREN.

HWND_DESKTOP

Track over the entire screen

Other

Track over specified window only.

WinTrackRect Parameter - hps

hps (**HPS**) - input

Presentation-space handle.

Used for drawing the clipping rectangle:

NULLHANDLE

The *hwnd* parameter is used to calculate a presentation space for tracking. It is assumed that tracking takes place within *hwnd* and that the style of this window is not WS_CLIPCHILDREN. Thus, when the drag rectangle appears, it is not clipped by any children within the window. If the window style is WS_CLIPCHILDREN and the application causes the drag rectangle to be clipped, it must explicitly pass an appropriate presentation space.

Other

Specified presentation-space handle.

WinTrackRect Parameter - ptiTrackinfo

ptiTrackinfo (**PTRACKINFO**) - in/out

Track information.

WinTrackRect Return Value - rc

rc (**BOOL**) - returns
Success indicator.

TRUE

Tracking successful.

FALSE

Tracking canceled, or the pointing device was already captured when this function was called.

Only one tracking rectangle can be in use at one time.

WinTrackRect - Parameters

hwnd (**HWND**) - input
Window handle where tracking is to take place.

It is assumed that the style of this window is not WS_CLIPCHILDREN.

HWND_DESKTOP

Track over the entire screen

Other

Track over specified window only.

hps (**HPS**) - input
Presentation-space handle.

Used for drawing the clipping rectangle:

NULLHANDLE

The *hwnd* parameter is used to calculate a presentation space for tracking. It is assumed that tracking takes place within *hwnd* and that the style of this window is not WS_CLIPCHILDREN. Thus, when the drag rectangle appears, it is not clipped by any children within the window. If the window style is WS_CLIPCHILDREN and the application causes the drag rectangle to be clipped, it must explicitly pass an appropriate presentation space.

Other

Specified presentation-space handle.

ptiTrackinfo (**PTRACKINFO**) - in/out
Track information.

rc (**BOOL**) - returns
Success indicator.

TRUE

Tracking successful.

FALSE

Tracking canceled, or the pointing device was already captured when this function was called.

Only one tracking rectangle can be in use at one time.

WinTrackRect - Remarks

The WinTrackRect call provides general-purpose pointing-device tracking. It draws a rectangle and enables the user to position the entire rectangle, or size a specific side or corner, as required. The resulting rectangle is then returned to the application, which can use this new information for size and position data. The window manager interface for moving and sizing windows by means of the wide sizing borders uses this function, for example.

This function enables the caller to control such limiting values as:

- A maximum and minimum tracking size
- Absolute tracking-position limits
- The tracking rectangle side widths
- A restriction of tracking rectangle movements to a predefined positional grid.

It automatically calls [WinLockWindowUpdate](#) to prevent output in the window *hwnd* and its descendants while tracking. When tracking has been completed, output is enabled before this function returns. It also determines which button of the pointing device is depressed at the start of the operation, and only completes the tracking operation when the same button is released.

If the parameter of the [TRACKINFO](#) structure specified by the value is included, the pointing device pointer is positioned at the center of the tracking rectangle. Otherwise, the pointing device pointer is not moved from its current position and *delta* is established between the pointing device position and the part of the tracking rectangle that it moves (the *delta* is kept constant).

While moving or sizing with the keyboard interface, the pointing device pointer is repositioned with the tracking rectangle's new size or position.

While tracking, these keys are active:

Enter	Accepts the new position or size.
Left cursor	Moves the pointing device pointer and tracking rectangle left. If the pointing device pointer is on the upper or lower edge of the tracking rectangle, the pointer is moved to the top-left or bottom-left corner respectively.
Up cursor	Moves the pointing device pointer and tracking rectangle up. If the pointing device pointer is on the left or right edge of the tracking rectangle, the pointer is moved to the top-left or top-right corner respectively.
Right cursor	Moves the pointing device pointer and tracking rectangle right. If the pointing device pointer is on the upper or lower edge of the tracking rectangle, the pointer is moved to the top-right or bottom-right corner respectively.
Down cursor	Moves the pointing device pointer and tracking rectangle down. If the pointing device pointer is on the left or right edge of the tracking rectangle, the pointer is moved to the bottom-left or bottom-right corner respectively.
Esc	Cancels the current tracking operation. The value of the tracking rectangle is undefined on exit.

The pointing device and the keyboard interface can be intermixed. The caller need not include the value to use the keyboard interface, as this value simply initializes the position of the pointing device pointer.

If is specified in the [TRACKINFO](#) structure, the interior of the tracking rectangle is restricted to multiples of the values of the parameters. The default values for these are the system font character width and half the system font character height, respectively.

Tracking movements using the keyboard arrow keys depend on whether or not is specified in the [TRACKINFO](#) structure. If not specified, the increments are the values of the keyboard arrow keys do not cause tracking.

The tracking rectangle is usually logically "on top" of objects it tracks, so that the user can see the old size and position while tracking the new. Thus, it is possible for a window "below" the tracking rectangle to be updated while part of the tracking rectangle is "above" it.

Because the tracking rectangle is drawn in exclusive-OR mode, no window can draw below the tracking rectangle (and thereby obliterate it) without first notifying the tracking code, because unwanted areas of the tracking rectangle can be left behind. If the window doing the drawing is clipped out from the window in which the tracking is occurring, this problem does not arise.

To prevent a window that is currently processing a [WM_PAINT](#) message drawing over the tracking rectangle, the tracking rectangle is considered as a system-wide resource, only one of which can be in use at any time. If there is a risk of the currently-updating window

drawing on the tracking rectangle, the tracking rectangle is removed while that window and its child windows update, and it is then replaced. This is done during the [WinBeginPaint](#) and [WinEndPaint](#) functions. If the tracking rectangle overlaps, it is removed in the [WinBeginPaint](#) function. In the [WinEndPaint](#) function, all the child windows are updated by means of the [WinUpdateWindow](#) function before the tracking rectangle is redrawn.

WinTrackRect has a modal loop within it. The loop has a HK_MSGFILTER hook and a MSGF_TRACK hook code.

Note: The rectangle tracked by this function stays within the specified tracking bounds and dimensions. If the rectangle passed is out of these bounds, or it is too large or too small, it is modified to a rectangle that meets these limits.

WinTrackRect - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinTrackRect - Example Code

This example shows how WinTrackRect can be used to allow a user size a rectangle on the screen.

```
#define INCL_WINTRACKRECT

#include <os2.h>

BOOL MyTrackRoutine(HAB hab, HPS hps, PRECTL rcl)
{
    TRACKINFO track;

    track.cxBorder = 4;
    track.cyBorder = 4; /* 4 pel wide lines used for rectangle */
    track.cxGrid = 1;
    track.cyGrid = 1; /* smooth tracking with mouse */
    track.cxKeyboard = 8;
    track.cyKeyboard = 8; /* faster tracking using cursor keys */
```

```

WinCopyRect(hab, &track.rclTrack, rcl);    /* starting point */

WinSetRect(hab, &track.rclBoundary, 0, 0, 640, 480); /* bounding rectangle */

track.ptlMinTrackSize.x = 10;
track.ptlMinTrackSize.y = 10; /* set smallest allowed size of rectangle */
track.ptlMaxTrackSize.x = 200;
track.ptlMaxTrackSize.y = 200; /* set largest allowed size of rectangle */

track.fs = TF_MOVE;

if (WinTrackRect(HWND_DESKTOP, hps, &track) )
{
    /* if successful copy final position back */
    WinCopyRect(hab, rcl, &track.rclTrack);
    return(TRUE);
}
else
{
    return(FALSE);
}
}

```

WinTranslateAccel

WinTranslateAccel - Syntax

This function translates a [WM_CHAR](#) message.

```

#define INCL_WINACCELERATORS /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;           /* Anchor-block handle. */
HWND     hwnd;          /* Destination window. */
HACCEL   haccelAccel;   /* Accelerator-table handle. */
PQMSG    pQmsg;         /* Message to be translated. */
BOOL     rc;            /* Success indicator. */

rc = WinTranslateAccel(hab, hwnd, haccelAccel,
    pQmsg);

```

WinTranslateAccel Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinTranslateAccel Parameter - hwnd

hwnd ([HWND](#)) - input
Destination window.

WinTranslateAccel Parameter - haccelAccel

haccelAccel ([HACCEL](#)) - input
Accelerator-table handle.

WinTranslateAccel Parameter - pQmsg

pQmsg ([PQMSG](#)) - in/out
Message to be translated.

WinTranslateAccel Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinTranslateAccel - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

hwnd ([HWND](#)) - input
Destination window.

hacclAccel ([HACCEL](#)) - input
Accelerator-table handle.

pQmsg ([PQMSG](#)) - in/out
Message to be translated.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinTranslateAccel - Remarks

This function translates *pQmsg* if it is a [WM_CHAR](#) message in the accelerator table *hacclAccel*. The message is translated into a [WM_COMMAND](#), [WM_SYSCOMMAND](#), or [WM_HELP](#) message, with *hwnd* identifying the destination window. Normally, this parameter is a frame-window handle. This function does not highlight menu items.

If *hacclAccel* equals NULL, the current accelerator table is assumed.

WinTranslateAccel returns TRUE if the message matches an accelerator in the table. *pQmsg* is modified by WinTranslateAccel if a match is found.

If a menu item exists that matches the accelerator-command value, and that item is disabled, *pQmsg* is translated to a [WM_NULL](#) message, rather than a [WM_COMMAND](#), [WM_SYSCOMMAND](#), or [WM_HELP](#) message. If the command is [WM_SYSCOMMAND](#) or [WM_HELP](#) (and if a [WM_SYSCOMMAND](#) or FID_SYSMENU child window is searched) the menu child window of *hwnd* that has the FID_MENU identifier is searched.

It is possible to have accelerators that do not correspond to items in a menu. If the command value does not match any items in the menu, the message is still translated.

Generally, applications do not have to call this function; it is usually called automatically by [WinGetMsg](#) and [WinPeekMsg](#), when a [WM_CHAR](#) message is received with the window handle of the active window as the first parameter. The standard frame window procedure always passes [WM_COMMAND](#) messages to the FID_CLIENT window. Because the message is physically changed by WinTranslateAccel, applications do not see the [WM_CHAR](#) messages that result in [WM_COMMAND](#), [WM_SYSCOMMAND](#), or [WM_HELP](#) messages.

WinTranslateAccel - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

PMERR_INVALID_HACCEL (0x101A)
An invalid accelerator-table handle was specified.

WinUnionRect

WinUnionRect - Syntax

This function calculates a rectangle that bounds the two source rectangles.

```
#define INCL_WINRECTANGLES /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
PRECTL   prclDest;     /* Bounding rectangle. */
PRECTL   prclSrc1;     /* First source rectangle. */
PRECTL   prclSrc2;     /* Second source rectangle. */
BOOL      rc;          /* Nonempty indicator. */

rc = WinUnionRect(hab, prclDest, prclSrc1,
                  prclSrc2);
```

WinUnionRect Parameter - hab

hab ([HAB](#)) - input
Anchor-block handle.

WinUnionRect Parameter - prclDest

prclDest ([PRECTL](#)) - output
Bounding rectangle.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) may also be used, if supported by the language.

WinUnionRect Parameter - prclSrc1

prclSrc1 ([PRECTL](#)) - input
First source rectangle.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) may also be used, if supported by the language.

WinUnionRect Parameter - prclSrc2

prclSrc2 ([PRECTL](#)) - input
Second source rectangle.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) may also be used, if supported by the language.

WinUnionRect Return Value - rc

rc ([BOOL](#)) - returns
Nonempty indicator.

TRUE

prclDest is a nonempty rectangle

FALSE

Error, or *prclDest* is an empty rectangle.

WinUnionRect - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

prclDest ([PRECTL](#)) - output
Bounding rectangle.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) may also be used, if supported by the language.

prclSrc1 ([PRECTL](#)) - input
First source rectangle.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) may also be used, if supported by the language.

prclSrc2 ([PRECTL](#)) - input
Second source rectangle.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) may also be used, if supported by the language.

rc ([BOOL](#)) - returns
Nonempty indicator.

TRUE

prclDest is a nonempty rectangle

FALSE

Error, or *prclDest* is an empty rectangle.

WinUnionRect - Remarks

prclSrc1 and *prclSrc2* must not be NULL pointers, although the rectangles they point to can be empty (see the [WinIsRectEmpty](#) function).

If one of the source rectangles is empty, the other is returned.

WinUnionRect - Example Code

This example uses the WinUnionRect call to find a rectangle that bounds two source rectangles.

```
#define INCL_WINRECTANGLES
#include <OS2.H>
HAB hab;
RECTL resultrcl;    /* result. */
RECTL rcla={25,     /* x coordinate of left-hand edge of */
```

```

        /* rectangle. */
    25,    /* y coordinate of bottom edge of    */
        /* rectangle. */
    125,   /* x coordinate of right-hand edge of */
        /* rectangle. */
    125};  /* y coordinate of top edge of rectangle. */

RECTL rclb = {15, /* x coordinate of left-hand edge of */
              /* rectangle. */
              15, /* y coordinate of bottom edge of    */
              /* rectangle. */
              125, /* x coordinate of right-hand edge of */
              /* rectangle. */
              125};

WinUnionRect(hab,
             &resultrcl,
             &rcla,
             &rclb);

```

WinUnlockSystem

WinUnlockSystem - Syntax

This function is specific to OS/2 Version 2.1 or higher.

This function causes an application program to attempt to unlock the system.

```

#define INCL_WINMESSAGEGR
#include <os2.h>

HAB      hab;           /* The application anchor block. */
PSZ      pszPassword;   /* Password string. */
BOOL     rc;            /* Return value. */

rc = WinUnlockSystem(hab, pszPassword);

```

WinUnlockSystem Parameter - hab

hab (**HAB**) - input
The application anchor block.

WinUnlockSystem Parameter - pszPassword

pszPassword (**PSZ**) - input
Password string.

WinUnlockSystem Return Value - rc

rc (**BOOL**) - returns
Return value.

TRUE

The system was successfully unlocked.

FALSE

An error occurred or the system was already in an unlocked state.

WinUnlockSystem - Parameters

hab (**HAB**) - input
The application anchor block.

pszPassword (**PSZ**) - input
Password string.

rc (**BOOL**) - returns
Return value.

TRUE

The system was successfully unlocked.

FALSE

An error occurred or the system was already in an unlocked state.

WinUnlockSystem - Remarks

This function causes an application program to attempt to unlock the system by passing a text string that can be compared against the system lockup password that is stored in an encrypted form by the system.

If the string passed in matches the system lockup password, the lockup dialog is dismissed and the user is able to use his machine. Otherwise, the system remains in the locked up state.

OS/2 does not provide a method for querying *pszPassword* to find out the password. It is up to the developer to ask the user what the password is.

In order to execute WinUnlockSystem after a WinLockupSystem has been called, the WinUnlockSystem must be called from a separate thread because WinLockupSystem will not return until a password has been entered from the keyboard.

The LockupHook hook allows a PM application to customize system lockups.

In order for the window to appear as the top most window on the lockup screen, the WS_CLIPSIBLINGS flag must be used for the *fStyle* parameter in the WinCreateWindow or WinCreateStdWindow call.

WinUpdateWindow

WinUpdateWindow - Syntax

This function forces the update of a window and its associated child windows.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwnd; /* Window handle. */
BOOL    rc;    /* Window-updated indicator. */

rc = WinUpdateWindow(hwnd);
```

WinUpdateWindow Parameter - hwnd

hwnd (**HWND**) - input
Window handle.

WinUpdateWindow Return Value - rc

rc (**BOOL**) - returns
Window-updated indicator.

TRUE	Window successfully updated
FALSE	Window not successfully updated.

WinUpdateWindow - Parameters

hwnd ([HWND](#)) - input
Window handle.

rc ([BOOL](#)) - returns
Window-updated indicator.

TRUE	Window successfully updated
FALSE	Window not successfully updated.

WinUpdateWindow - Remarks

If *hwnd* is an asynchronous window (that is, it does not have a style of [WS_SYNCPAINT](#)), only it and its asynchronous children are updated. They are sent [WM_PAINT](#) messages from this function. If the window is owned by a different thread from the thread issuing the call, the message is sent asynchronously (using [WinPostMsg](#)) and not synchronously (using [WinSendMessage](#)).

If the window does not have an invalid region, a [WM_PAINT](#) message might not be sent.

If *hwnd* is a child of a nonclip-children parent, the update region of *hwnd* is subtracted from the update region of the parent, if the parent has one. This is so that any parent-window drawing after *hwnd* does not draw over whatever is drawn by *hwnd*.

WinUpdateWindow - Errors

Possible returns from [WinGetLastError](#)

[PMERR_INVALID_HWND](#) (0x1001)
An invalid window handle was specified.

WinUpper

WinUpper - Syntax

This function converts a string to uppercase.

```
#define INCL_WINCOUNTRY /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
ULONG    ulCodepage;   /* Code page. */
ULONG    ulCountry;    /* Country code. */
PSZ      pszString;    /* String to be converted to uppercase. */
ULONG    ulRetLen;     /* Length of converted string. */

ulRetLen = WinUpper(hab, ulCodepage, ulCountry,
                    pszString);
```

WinUpper Parameter - hab

hab (**HAB**) - input
Anchor-block handle.

WinUpper Parameter - ulCodepage

ulCodepage (**ULONG**) - input
Code page.

- 0
Use the current-process code page
- Other
Use the specified code page.

WinUpper Parameter - ulCountry

ulCountry (**ULONG**) - input
Country code.

- 0
Use the default country code specified in CONFIG.SYS
- Other
Use the specified country code.

WinUpper Parameter - pszString

pszString (PSZ) - in/out
String to be converted to uppercase.

WinUpper Return Value - ulRetLen

ulRetLen (ULONG) - returns
Length of converted string.

WinUpper - Parameters

hab (HAB) - input
Anchor-block handle.

ulCodepage (ULONG) - input
Code page.

- 0 Use the current-process code page
- Other Use the specified code page.

ulCountry (ULONG) - input
Country code.

- 0 Use the default country code specified in CONFIG.SYS
- Other Use the specified country code.

pszString (PSZ) - in/out
String to be converted to uppercase.

ulRetLen (ULONG) - returns
Length of converted string.

WinUpper - Remarks

The following is the list of valid code pages:

Country	Code Page
Canadian-French	863
Desktop Publishing	1004
Iceland	861
Latin 1 Multilingual	850
Latin 2 Multilingual	852
Nordic	865
Portuguese	860
Turkey	857
U.S. (IBM PC)	437

Code page 1004 is compatible with Microsoft** Windows**.

The following EBCDIC code pages, based on character set 697, are also available for output:

Country	Code Page
Austrian/German	273
Belgian	500
Brazil	037
Czechoslovakia	870
Danish/Norwegian	277
Finnish/Swedish	278

WinUpperChar

WinUpperChar - Syntax

This function translates a character to uppercase.

```

#define INCL_WINCOUNTRY /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
ULONG    ulCodepage;   /* Code page. */
ULONG    ulCountry;    /* Country code. */
ULONG    ulInchar;     /* Character to be translated to uppercase. */
ULONG    ulOutchar;    /* Translated character. */

ulOutchar = WinUpperChar(hab, ulCodepage,
                        ulCountry, ulInchar);

```

WinUpperChar Parameter - hab

hab (**HAB**) - input
Anchor-block handle.

WinUpperChar Parameter - ulCodepage

ulCodepage (**ULONG**) - input
Code page.

- 0 Use the current-process code page
- Other Use the specified code page.

WinUpperChar Parameter - ulCountry

ulCountry (**ULONG**) - input
Country code.

- 0 Use the default country code specified in CONFIG.SYS
- Other Use the specified country code.

WinUpperChar Parameter - ulInchar

ulInchar (**ULONG**) - input
Character to be translated to uppercase.

WinUpperChar Return Value - ulOutchar

ulOutchar ([ULONG](#)) - returns
Translated character.

0	Error occurred
Other	The translated character.

WinUpperChar - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

ulCodepage ([ULONG](#)) - input
Code page.

0	Use the current-process code page
Other	Use the specified code page.

ulCountry ([ULONG](#)) - input
Country code.

0	Use the default country code specified in CONFIG.SYS
Other	Use the specified country code.

ullnchar ([ULONG](#)) - input
Character to be translated to uppercase.

ulOutchar ([ULONG](#)) - returns
Translated character.

0	Error occurred
Other	The translated character.

WinUpperChar - Remarks

The case-mapping used is the same as provided by the OS/2 DosCaseMap call.

WinUpperChar - Errors

Possible returns from [WinGetLastError](#)

PMERR_INV_CODEPAGE (0x2052)
An invalid code-page was specified.

PMERR_INVALID_STRING_PARM (0x100B)
The specified string parameter is invalid.

WinValidateRect

WinValidateRect - Syntax

This function subtracts a rectangle from the update region of an asynchronous paint window, marking that part of the window as visually valid.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwnd;          /* Handle of window whose update region is changed. */
PRECTL    prclRect;      /* Rectangle to be subtracted from the window's update region. */
BOOL      fIncludeClippedChildren; /* Validation-scope indicator. */
BOOL      rc;            /* Success indicator. */

rc = WinValidateRect(hwnd, prclRect, fIncludeClippedChildren);
```

WinValidateRect Parameter - hwnd

hwnd (**HWND**) - input

Handle of window whose update region is changed.

If this parameter is **HWND_DESKTOP** or a desktop-window handle, the function applies to the whole screen (or desktop).

WinValidateRect Parameter - prclRect

prclRect (**PRECTL**) - input

Rectangle to be subtracted from the window's update region.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type **WRECT** may also be used, if supported by the language.

WinValidateRect Parameter - fIncludeClippedChildren

fIncludeClippedChildren (**BOOL**) - input

Validation-scope indicator.

TRUE	Include descendants of <i>hwnd</i> in the valid rectangle
FALSE	Include descendants of <i>hwnd</i> in the valid rectangle, only if parent is not WS_CLIPCHILDREN.

WinValidateRect Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinValidateRect - Parameters

hwnd ([HWND](#)) - input
Handle of window whose update region is changed.

If this parameter is HWND_DESKTOP or a desktop-window handle, the function applies to the whole screen (or desktop).

prclRect ([PRECTL](#)) - input
Rectangle to be subtracted from the window's update region.

Note: The value of each field in this structure must be in the range -32 768 through 32 767. The data type [WRECT](#) may also be used, if supported by the language.

fIncludeClippedChildren ([BOOL](#)) - input
Validation-scope indicator.

TRUE	Include descendants of <i>hwnd</i> in the valid rectangle
FALSE	Include descendants of <i>hwnd</i> in the valid rectangle, only if parent is not WS_CLIPCHILDREN.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinValidateRect - Remarks

The call is not used for CS_SYNCPAINT windows.

This function has no effect on the window if any part of the window has been made invalid since the last call to [WinBeginPaint](#), [WinQueryUpdateRect](#), or [WinQueryUpdateRegion](#).

WinValidateRect - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

PMERR_INVALID_FLAG (0x1019)
An invalid bit was set for a parameter. Use constants defined by PM for options, and do not set any reserved bits.

WinValidateRect - Example Code

The window needs painting. This is done asynchronously on the drawing thread. The window update region is copied into a local region and passed to the drawing thread. The window must be validated now (to prevent further unnecessary paint messages).

```
#define INCL_WINWINDOWMGR
#include <OS2.H>
HRGN hrgnUpdate;
HPS hps;
HWND hwnd;
/* Window needs paint */
case WM_PAINT:

/* assume we stop any asynchronous drawing. */
/* by posting a message to the asynchronous */
/* drawing thread. */

hrgnUpdate=(HRGN)GpiCreateRegion(hps, /* Create empty region */
                                0L,
                                (PRECTL)NULL);
```

```

WinQueryUpdateRegion(hwnd,          /* Save the window update */
                    hrgnUpdate);    /* region.                */

WinValidateRect(hwnd,              /* Validate window now to */
                (PRECTL)NULL,      /* stop more paint msgs */
                TRUE);

/* assume a message is posted to the drawing thread, passing */
/* the update region: (MPARAM)hrgnUpdate.                    */

mr = (MRESULT) 0L;                /* Message processed      */
break;                            /* End window painting    */

```

WinValidateRegion

WinValidateRegion - Syntax

This function subtracts a region from the update region of an asynchronous paint window, marking that part of the window as visually valid.

```

#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwnd;                /* Handle of window whose update region is changed. */
HRGN    hrgn;                /* Handle of subtracted region. */
BOOL    fIncludeClippedChildren; /* Validation-scope indicator. */
BOOL    rc;                  /* Success indicator. */

rc = WinValidateRegion(hwnd, hrgn, fIncludeClippedChildren);

```

WinValidateRegion Parameter - hwnd

hwnd (HWND) - input
Handle of window whose update region is changed.

If this parameter is HWND_DESKTOP or a desktop window handle, the function applies to the whole screen (or desktop).

WinValidateRegion Parameter - hrgn

hrgn (HRGN) - input
Handle of subtracted region.

This is the region that is subtracted from the window's update region.

WinValidateRegion Parameter - fIncludeClippedChildren

fIncludeClippedChildren (BOOL) - input
Validation-scope indicator.

- | | |
|-------|--|
| TRUE | Include descendants of <i>hwnd</i> in the valid region |
| FALSE | Include descendants of <i>hwnd</i> in the valid region, only if parent is not WS_CLIPCHILDREN. |

WinValidateRegion Return Value - rc

rc (BOOL) - returns
Success indicator.

- | | |
|-------|-----------------------|
| TRUE | Successful completion |
| FALSE | Error occurred. |

WinValidateRegion - Parameters

hwnd (HWND) - input
Handle of window whose update region is changed.

If this parameter is HWND_DESKTOP or a desktop window handle, the function applies to the whole screen (or desktop).

hrgn (HRGN) - input
Handle of subtracted region.

This is the region that is subtracted from the window's update region.

flIncludeClippedChildren ([BOOL](#)) - input
Validation-scope indicator.

TRUE

Include descendants of *hwnd* in the valid region

FALSE

Include descendants of *hwnd* in the valid region, only if parent is not WS_CLIPCHILDREN.

rc ([BOOL](#)) - returns
Success indicator.

TRUE

Successful completion

FALSE

Error occurred.

WinValidateRegion - Remarks

The call is not used for CS_SYNCPAINT windows.

The call has no effect on the window if any part of the window has been made invalid since the last call to [WinBeginPaint](#), [WinQueryUpdateRect](#), or [WinQueryUpdateRegion](#).

WinValidateRegion - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)

An invalid window handle was specified.

PMERR_HRGN_BUSY (0x2034)

An internal region busy error was detected. The region was locked by one thread during an attempt to access it from another thread.

PMERR_INVALID_FLAG (0x1019)

An invalid bit was set for a parameter. Use constants defined by PM for options, and do not set any reserved bits.

WinValidateRegion - Example Code

This example shows how an application can incrementally repaint an asynchronous-paint window one area at a time. While a window is invalid (has a non-null update region), WM_PAINT messages are returned by WinGetMsg. The application uses WinQueryUpdateRegion to obtain a region that requires repainting, and WinValidateRegion to validate the region (reset the update region to null).

```
#define INCL_WINWINDOWMGR
#define INCL_GPIREGIONS
#include <OS2.H>

WinWaitEventSem

WinWaitEventSem - Syntax

This function waits for an event semaphore to be posted for a Presentation Manager message to be received.

```
#define INCL_WINMESSAGEGR
#include <os2.h>

HEV      hev;          /* The handle of the event semaphore to wait for. */
ULONG    ulTimeout;    /* Time-out in milliseconds. */
APIRET   rc;           /* Return Code. */

rc = WinWaitEventSem(hev, ulTimeout);
```

WinWaitEventSem Parameter - hev

hev ([HEV](#)) - input
The handle of the event semaphore to wait for.

WinWaitEventSem Parameter - ulTimeout

ulTimeout ([ULONG](#)) - input
Time-out in milliseconds.

This is the maximum amount of time the user wants to allow the thread to be blocked.

This parameter can also have the following values:

SEM_IMMEDIATE_RETURN (0)
WinWaitMuxWaitSem returns without blocking the calling thread.
SEM_INDEFINITE_WAIT (-1)
WinWaitMuxWaitSem blocks the calling thread indefinitely.

WinWaitEventSem Return Value - rc

rc ([APIRET](#)) - returns
Return Code.

WinWaitEventSem returns the following values:

0	NO_ERROR
6	ERROR_INVALID_HANDLE
8	ERROR_NOT_ENOUGH_MEMORY
95	ERROR_INTERRUPT
640	ERROR_TIMEOUT

WinWaitEventSem - Parameters

hev ([HEV](#)) - input

The handle of the event semaphore to wait for.

ulTimeout ([ULONG](#)) - input

Time-out in milliseconds.

This is the maximum amount of time the user wants to allow the thread to be blocked.

This parameter can also have the following values:

SEM_IMMEDIATE_RETURN (0)

WinWaitMuxWaitSem returns without blocking the calling thread.

SEM_INDEFINITE_WAIT (-1)

WinWaitMuxWaitSem blocks the calling thread indefinitely.

rc ([APIRET](#)) - returns

Return Code.

WinWaitEventSem returns the following values:

0	NO_ERROR
6	ERROR_INVALID_HANDLE
8	ERROR_NOT_ENOUGH_MEMORY
95	ERROR_INTERRUPT
640	ERROR_TIMEOUT

WinWaitEventSem - Remarks

WinWaitEventSem is similar to DosWaitEventSem and enables a thread to wait for an event semaphore to be posted or for a window message sent by [WinSendMsg](#) from another thread to be received.

This function can be called by any thread in the process that created the semaphore. Threads in other processes can also call this function, but they must first gain access to the semaphore by calling DosOpenEventSem.

Since the processing of a window message may take longer than the value specified by the *ulTimeout* parameter, this function may not return within the time specified by that value.

If the main thread (which normally processes messages) is waiting on a semaphore for a prolonged period of time, messages will not be processed, and the "Bad App" dialog can occur. This is expected behavior. To avoid this, a message-box can be displayed telling the user that the window is being initialized. While the window loads, that message box can process the incoming system messages.

WinWaitEventSem - Example Code

This example causes the calling thread to wait until the specified event semaphore is posted. Assume that the handle of the semaphore has been placed into *hev* already.

ulTimeout is the number of milliseconds that the calling thread will wait for the event semaphore to be posted. If the specified event semaphore is not posted during this time interval, the request times out.

```
#define INCL_DOSSEMAPHORES /* Semaphore values */
#define INCL_WINMESSAGEGR
#include <os2.h>
#include <stdio.h>

#ifdef ERROR_TIMEOUT
#define ERROR_TIMEOUT 640
#define ERROR_INTERRUPT 95
#endif

HEV hev; /* Event semaphore handle */
ULONG ulTimeout; /* Number of milliseconds to wait */
ULONG rc; /* Return code */

ulTimeout = 60000; /* Wait for a maximum of 1 minute */

rc = WinWaitEventSem(hev, ulTimeout);

if (rc == ERROR_TIMEOUT)
{
    printf("WinWaitEventSem call timed out");
    return;
}

if (rc == ERROR_INTERRUPT)
{
    printf("WinWaitEventSem call was interrupted");
    return;
}

if (rc != 0)
{
    printf("WinWaitEventSem error: return code = %ld", rc);
    return;
}

WinWaitMsg

WinWaitMsg - Syntax

This function waits for a filtered message.

```
#define INCL_WINMESSAGEGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HAB      hab;          /* Anchor-block handle. */
ULONG    ulFirst;       /* First message identity. */
ULONG    ulLast;        /* Last message identity. */
BOOL     rc;            /* Success indicator. */

rc = WinWaitMsg(hab, ulFirst, ulLast);
```

WinWaitMsg Parameter - hab

hab (**HAB**) - input
Anchor-block handle.

WinWaitMsg Parameter - ulFirst

ulFirst (**ULONG**) - input
First message identity.

WinWaitMsg Parameter - ulLast

ulLast (**ULONG**) - input
Last message identity.

WinWaitMsg Return Value - rc

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinWaitMsg - Parameters

hab ([HAB](#)) - input
Anchor-block handle.

ulFirst ([ULONG](#)) - input
First message identity.

ulLast ([ULONG](#)) - input
Last message identity.

rc ([BOOL](#)) - returns
Success indicator.

TRUE	Successful completion
FALSE	Error occurred.

WinWaitMsg - Remarks

This function causes the current thread to wait for a message to arrive on the message queue associated with *hab*. This must be the next message since the queue was last inspected by a *rc* return from [WinGetMsg](#) or [WinPeekMsg](#). It must also conform to the filtering criteria specified by *ulFirst* and *ulLast*.

For details of the filtering performed by *ulFirst* and *ulLast*, see the [WinGetMsg](#) function.

WinWaitMsg - Example Code

In this example the pointer is kept hidden until mouse activity is detected. The WinWaitMsg call is used to wait for any mouse message.

```
#define INCL_WINWINDOWMGR
#define INCL_WINPOINTERS
#define INCL_WINDESKTOP
#define INCL_WININPUT
#include <OS2.H>

HWND hwnd;
HPOINTER hpointer;
HAB hab;

/* Get the pointer handle */
hpointer = WinQueryPointer(HWND_DESKTOP);

/* Hide the mouse */
WinShowPointer(hwnd,FALSE);

/* All the mouse messages from WM_MOUSEFIRST */
/* to WM_BUTTON3DBLCLK inclusive */
WinWaitMsg(hab,
            WM_MOUSEFIRST,
            WM_BUTTON3DBLCLK);

/* If there has been any mouse activity, show the mouse */
WinShowPointer(hwnd,TRUE);
```

WinWaitMuxWaitSem

WinWaitMuxWaitSem - Syntax

WinWaitMuxWaitSem waits for a muxwait semaphore to clear or for a Presentation Manager message.

```
#define INCL_WINMESSAGEGR
#include <os2.h>

HMUX      hmutex;      /* The handle of the muxwait semaphore to wait for. */
ULONG     ulTimeout;   /* Time-out in milliseconds. */
PULONG    pulUser;     /* Pointer to receive the user field. */
APIRET    ulrc;        /* Return Code. */

ulrc = WinWaitMuxWaitSem(hmutex, ulTimeout,
                        pulUser);
```

WinWaitMuxWaitSem Parameter - hmutex

hmutex (**HMUX**) - input
The handle of the muxwait semaphore to wait for.

WinWaitMuxWaitSem Parameter - ulTimeout

ulTimeout (**ULONG**) - input
Time-out in milliseconds.

This is the maximum amount of time the user wants to allow the thread to be blocked.

This parameter can also have the following values:

SEM_IMMEDIATE_RETURN (0)
WinWaitMuxWaitSem returns without blocking the calling thread.
SEM_INDEFINITE_WAIT (-1)
WinWaitMuxWaitSem blocks the calling thread indefinitely.

WinWaitMuxWaitSem Parameter - pulUser

pulUser (**PULONG**) - output
Pointer to receive the user field.

A pointer to receive the user field (from the muxwait semaphore data structure) of the semaphore that was posted or released.

If DCMW_WAIT_ANY was specified in the *flAttr* parameter when the muxwait semaphore was created, this will be the user field of the semaphore that was posted or released. If the muxwait semaphore consists of mutex semaphores, any mutex semaphore that is released is owned by the caller.

If DCMW_WAIT_ALL was specified in the *flAttr* parameter when the muxwait semaphore was created, this will be the user field of the *last* semaphore that was posted or released. (If the thread did not block, the last semaphore that was posted or released will also be the last semaphore in the muxwait-semaphore list.) If the muxwait semaphore consists of mutex semaphores, all of the mutex semaphores that are released are owned by the caller.

WinWaitMuxWaitSem Return Value - ulrc

ulrc ([APIRET](#)) - returns
Return Code.

WinWaitMuxWaitSem returns the following values:

0	NO_ERROR
6	ERROR_INVALID_HANDLE
8	ERROR_NOT_ENOUGH_MEMORY
87	ERROR_INVALID_PARAMETER
95	ERROR_INTERRUPT
103	ERROR_TOO_MANY_SEM_REQUESTS
105	ERROR_SEM_OWNER_DIED
286	ERROR_EMPTY_MUXWAIT
287	ERROR_MUTEX_OWNED
292	ERROR_WRONG_TYPE
640	ERROR_TIMEOUT

WinWaitMuxWaitSem - Parameters

hmutex ([HMXU](#)) - input
The handle of the muxwait semaphore to wait for.

ulTimeout ([ULONG](#)) - input
Time-out in milliseconds.

This is the maximum amount of time the user wants to allow the thread to be blocked.

This parameter can also have the following values:

SEM_IMMEDIATE_RETURN (0)	WinWaitMuxWaitSem returns without blocking the calling thread.
SEM_INDEFINITE_WAIT (-1)	WinWaitMuxWaitSem blocks the calling thread indefinitely.

pulUser ([PULONG](#)) - output
Pointer to receive the user field.

A pointer to receive the user field (from the muxwait semaphore data structure) of the semaphore that was posted or released.

If DCMW_WAIT_ANY was specified in the *flAttr* parameter when the muxwait semaphore was created, this will be the user field of the semaphore that was posted or released. If the muxwait semaphore consists of mutex semaphores, any mutex semaphore that is released is owned by the caller.

If DCMW_WAIT_ALL was specified in the *flAttr* parameter when the muxwait semaphore was created, this will be the user field of the *last* semaphore that was posted or released. (If the thread did not block, the last semaphore that was posted or released will also be the last semaphore in the muxwait-semaphore list.) If the muxwait semaphore consists of mutex semaphores, all of the mutex semaphores that are released are owned by the caller.

ulrc ([APIRET](#)) - returns
Return Code.

WinWaitMuxWaitSem returns the following values:

0	NO_ERROR
6	ERROR_INVALID_HANDLE
8	ERROR_NOT_ENOUGH_MEMORY
87	ERROR_INVALID_PARAMETER
95	ERROR_INTERRUPT
103	ERROR_TOO_MANY_SEM_REQUESTS
105	ERROR_SEM_OWNER_DIED
286	ERROR_EMPTY_MUXWAIT
287	ERROR_MUTEX_OWNED
292	ERROR_WRONG_TYPE
640	ERROR_TIMEOUT

WinWaitMuxWaitSem - Remarks

WinWaitMuxWaitSem is similar to DosWaitMuxWaitSem and enables a thread to wait for a muxwait semaphore to clear or for a window message sent by the WinSendMsg function from another thread to be received.

This function can be issued by any thread in the process that created the semaphore. Threads in other processes can also issue this function, but they must first gain access to the semaphore by issuing DosOpenMuxWaitSem.

Since the processing of a window message may take longer than the value specified by the *ulTimeout* parameter, this function may not return within the time specified by that value.

If the main thread (which normally processes messages) is waiting on a semaphore for a prolonged period of time, messages will not be processed, and the "Bad App" dialog can occur. This is expected behavior. To avoid this, a message-box can be displayed telling the user that the window is being initialized. While the window loads, that message box can process the incoming system messages.

WinWindowFromDC

WinWindowFromDC - Syntax

This function returns the handle of the window corresponding to a particular device context.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
```

```
#include <os2.h>

HDC     hdc; /* Device-context handle. */
HWND    hwnd; /* Window handle. */

hwnd = WinWindowFromDC(hdc);
```

WinWindowFromDC Parameter - hdc

hdc ([HDC](#)) - input
Device-context handle.

The device context must first be opened by the [WinOpenWindowDC](#) function.

WinWindowFromDC Return Value - hwnd

hwnd ([HWND](#)) - returns
Window handle.

NULLHANDLE

Error occurred. For example, the device context has not been opened by the [WinOpenWindowDC](#) function.

Other

Window handle.

WinWindowFromDC - Parameters

hdc ([HDC](#)) - input
Device-context handle.

The device context must first be opened by the [WinOpenWindowDC](#) function.

hwnd ([HWND](#)) - returns
Window handle.

NULLHANDLE

Error occurred. For example, the device context has not been opened by the [WinOpenWindowDC](#) function.

Other

Window handle.

WinWindowFromDC - Errors

Possible returns from [WinGetLastError](#)

PMERR_INV_HPS (0x207F)

An invalid presentation-space handle was specified.

PMERR_INV_HDC (0x207C)

An invalid device-context handle or (micro presentation space) presentation-space handle was specified.

WinWindowFromID

WinWindowFromID - Syntax

This function returns the handle of the child window with the specified identity.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND    hwndParent; /* Parent-window handle. */
ULONG    id;        /* Identity of the child window. */
HWND    hwnd;        /* Window handle. */

hwnd = WinWindowFromID(hwndParent, id);
```

WinWindowFromID Parameter - hwndParent

hwndParent (**HWND**) - input
Parent-window handle.

WinWindowFromID Parameter - id

id (**ULONG**) - input
Identity of the child window.

It must be greater or equal to 0 and less or equal to 0xFFFF.

WinWindowFromID Return Value - hwnd

hwnd (**HWND**) - returns
Window handle.

NULLHANDLE	No child window of the specified identity exists
Other	Child-window handle.

WinWindowFromID - Parameters

hwndParent ([HWND](#)) - input
Parent-window handle.

id ([ULONG](#)) - input
Identity of the child window.

It must be greater or equal to 0 and less or equal to 0xFFFF.

hwnd ([HWND](#)) - returns
Window handle.

NULLHANDLE
No child window of the specified identity exists

Other
Child-window handle.

WinWindowFromID - Remarks

To obtain the window handle for an item within a dialog box, set *hwndParent* to the dialog-box window's handle, and set *id* to the identity of the item in the dialog template.

WinWindowFromID - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

WinWindowFromPoint

WinWindowFromPoint - Syntax

This function finds the window below a specified point, that is a descendant of a specified window.

```
#define INCL_WINWINDOWMGR /* Or use INCL_WIN, INCL_PM, */
#include <os2.h>

HWND      hwndParent;      /* Window handle whose child windows are to be tested. */
PPOINTL   pptlPoint;       /* The point to be tested. */
BOOL      fEnumChildren;   /* Test control. */
HWND      hwndFound;       /* Window handle beneath pptlPoint. */

hwndFound = WinWindowFromPoint(hwndParent,
    pptlPoint, fEnumChildren);
```

WinWindowFromPoint Parameter - hwndParent

hwndParent ([HWND](#)) - input

Window handle whose child windows are to be tested.

HWND_DESKTOP

The desktop-window handle, implying that all main windows are tested. In this instance, *pptlPoint* must be relative to the bottom left corner of the screen.

Other

Parent-window handle.

WinWindowFromPoint Parameter - pptlPoint

pptlPoint ([PPOINTL](#)) - input

The point to be tested.

Specified in window coordinates relative to the window specified by the *hwndParent* parameter.

WinWindowFromPoint Parameter - fEnumChildren

fEnumChildren ([BOOL](#)) - input

Test control.

TRUE

Test all the descendant windows, including child windows of child windows

FALSE

Test only the immediate child windows.

WinWindowFromPoint Return Value - hwndFound

hwndFound ([HWND](#)) - returns

Window handle beneath *pptlPoint*.

NULLHANDLE

pptlPoint is outside *hwndParent*

Parent

pptlPoint is not inside any of the children of *hwndParent*

Other

Window handle is beneath *pptlPoint*.

WinWindowFromPoint - Parameters

hwndParent (HWND)	- input
Window handle whose child windows are to be tested.	
HWND_DESKTOP	The desktop-window handle, implying that all main windows are tested. In this instance, <i>pptlPoint</i> must be relative to the bottom left corner of the screen.
Other	Parent-window handle.
pptlPoint (PPOINTL)	- input
The point to be tested.	
Specified in window coordinates relative to the window specified by the <i>hwndParent</i> parameter.	
fEnumChildren (BOOL)	- input
Test control.	
TRUE	Test all the descendant windows, including child windows of child windows
FALSE	Test only the immediate child windows.
hwndFound (HWND)	- returns
Window handle beneath <i>pptlPoint</i> .	
NULLHANDLE	<i>pptlPoint</i> is outside <i>hwndParent</i>
Parent	<i>pptlPoint</i> is not inside any of the children of <i>hwndParent</i>
Other	Window handle is beneath <i>pptlPoint</i> .

WinWindowFromPoint - Remarks

This function checks only the descendants of the specified window.

WinWindowFromPoint - Errors

Possible returns from [WinGetLastError](#)

PMERR_INVALID_HWND (0x1001)
An invalid window handle was specified.

Message Processing

Messages are processed by window and dialog procedures.

Every window has a window procedure. Windows can also be combined into standard windows or dialog boxes. These are special cases of groups of windows that also have their own procedures. A window or dialog procedure must be capable of processing any message. This can be achieved by delegating some message types to the default window, or dialog, procedures by use of the [WinDefWindowProc](#) and [WinDefDlgProc](#) functions respectively.

Control windows are a special type of child windows. They take the form of objects such as buttons, scroll bars, list boxes, and text entry fields. These child windows process mouse and keyboard input and notify its owner of significant input events. Procedures for these child window controls are inside the Presentation Manager and are often called system-provided window procedures.

All messages have the same form as [QMSG](#). structure.

Message Types

There are two types of window procedure message processing:

- Default window and dialog procedure message processing
- Control window message processing.

These types are described in [Default Window and Dialog Procedure Message Processing](#) and [Control Window Message Processing](#). The messages are described in the message groups found on the Contents.

Default Window and Dialog Procedure Message Processing

These window procedures provide default processing for application window procedures:

- Default window and dialog procedure
- Language support window and dialog procedures, which are used if the application specifies a null window procedure
- Default AVIO window procedure.

These messages are described in [Default Window Procedure Message Processing](#). The system-provided window procedures take no action on messages that are not defined in this chapter, and return NULL.

Control Window Message Processing

Controls are predefined classes of child windows that any application can use for input and output. These control classes are predefined:

WC_BUTTON	Consists of buttons and boxes that the operator can select by clicking the pointing device or using the keyboard. These messages are described in Button Control Window Processing .
WC_CIRCULARSLIDER	Consists of a visual component whose specific purpose is to allow a user to set, display, or modify a value by moving the slider arm around the circular slider dial. Messages are described in Circular Slider Control Window Messages .
WC_COMBOBOX	Consists of an entry field control and a list box control merged into a single control. The list, which is usually limited in size, is displayed below the entry field and offset one dialog box unit to its right. These messages are described in Combination-Box Control Window Processing .
WC_CONTAINER	Consists of a visual component whose specific purpose is to hold objects such as executable programs, word processing files, graphics images, and database records. Messages are described in Container Control Window Processing .
WC_ENTRYFIELD	Consists of a single line of text that the operator can edit. These messages are

described in [Entry Field Control Window Processing](#).

WC_FRAME	Consists of a composite window. These messages are described in Frame Control Window Processing .
WC_LISTBOX	Presents a list of text items from which the operator can make selections. These messages are described in List Box Control Window Processing .
WC_MENU	Presents a list of items, which may be text displayed horizontally as action bars or vertically as pull-down menus. Menus are usually used to provide a command interface to applications. These messages are described in Menu Control Window Processing .
WC_MLE	Consists of a rectangular window that displays multiple lines of text that the operator can edit. When it has the focus, the cursor marks the current <i>insertion</i> or <i>replacement</i> point. These messages are described in Multi-Line Entry Field Control Window Processing .
WC_NOTEBOOK	Consists of a visual component whose specific purpose is to organize information on individual pages so that a user can find and display that information quickly and easily. Messages are described in Notebook Control Window Processing .
WC_SCROLLBAR	Consists of window scroll bars that allow the operator to make a request to scroll the contents of an associated window. These messages are described in Scroll Bar Control Window Processing .
WC_SLIDER	Consists of a visual component whose specific purpose is to allow a user to set, display, or modify a value by moving the slider arm along the slider shaft. Messages are described in Slider Control Window Processing .
WC_SPINBUTTON	Presents a scrollable ring of choices from which the operator can select. These messages are described in Spin Button Control Window Processing .
WC_STATIC	Consists of simple display items that do not respond to keyboard or pointing device events. These messages are described in Static Control Window Processing .
WC_TITLEBAR	Displays the window title or caption and allows the operator to move its owner. These messages are described in Title Bar Control Window Processing .
WC_VALUESET	Consists of a visual component whose specific purpose is to allow a user to select one choice from a group of mutually exclusive choices. A value set can use graphical images (bit maps or icons), as well as colors, text, and numbers, to represent the items that a user can select. Messages are described in Value Set Control Window Processing .

Owner-Notification Messages

Controls are useful because they notify their owners when significant events take place. A control notifies its owner by sending a WM_CONTROL message or by posting a WM_COMMAND or WM_HELP message.

- WM_CONTROL
- WM_COMMAND

Param2 contains information that indicates the source of the WM_COMMAND message:

CMDSRC_PUSHBUTTON	Posted by a pushbutton control
CMDSRC_MENU	Posted by a menu control
CMDSRC_ACCELERATOR	Posted by WinTranslateAccel
CMDSRC_FONTDLG	Posted by a font dialog.
CMDSRC_OTHER	Other source.

- WM_HELP

Param1 contains information that indicates the source of the WM_HELP message:

CMDSRC_PUSHBUTTON	Posted by a pushbutton control
CMDSRC_MENU	Posted by a menu control
CMDSRC_ACCELERATOR	Posted by WinTranslateAccel
CMDSRC_OTHER	Other source.

Notation Conventions

Each message description contains:

Name

The message name; a 2-byte identity unique to a message.

Some message identity values are reserved for the use of the operating system, some are available for use by an application. See **Reserved Messages** under [Default Window Procedure Message Processing](#).

For all messages, the first two or three characters of the name indicate the type of window that is related to the message; for example:

LM	List box control
SBM	Scroll bar control.

Cause

The principal reason that caused the generation of the message.

Parameters

Input and output parameters pertinent to the message.

There are always two parameters (*param1* and *param2*) and one *return* value. Any or all of the parameters can be NULL.

Remarks

An explanation of the relationship between the parameters in the context of the message and an indication of the expected processing of the message.

Default

A definition of how the default window procedures (provided by the system) process the message.

Note: A message is not equivalent to a call of the same name.

Button Control Window Processing

This system-provided window procedure processes the actions on a button control (WC_BUTTON).

For information on button control data see [BTNCDATA](#).

Purpose

A button control is a small rectangular child window representing a button that the operator can "switch" on or off. Button controls can be used alone or in groups, and can either be labeled or appear without text. Button controls typically change appearance when the operator clicks a pointing device on them or pressing the space bar when the button has the keyboard focus.

Buttons can be disabled to prevent them from responding when the operator clicks on them. Disabled buttons are displayed using a different emphasis technique (for example, color or half-toning).

Button Control Styles

These button control styles are available:

BS_AUTOCHECKBOX

An automatic check box automatically toggles its state whenever the user clicks on it.

BS_AUTORADIOBUTTON

When clicked, an automatic radio button automatically checks itself and unchecks all other radio buttons in the same group.

BS_AUTOSIZE

Buttons with this style are sized automatically to make sure the contents fit.

If BS_AUTOSIZE is selected when the button is created, and a -1 is specified for either the parameter of [WinCreateWindow](#), (or when creating the button as a resource) then the button's optimal size is calculated to display the its contents.

BS_AUTO3STATE

An automatic three-state check box automatically toggles its state when the user clicks on it.

BS_BITMAP

Places a bit map instead of text on the push button control. This style works only with the BS_PUSHBUTTON.

BS_CHECKBOX

A check box is a small square with a character string to the right. If it is checked, a small black box appears inside the small square. When the box or string is clicked, by clicking on it with the pointing device or pressing the keyboard spacebar when it is active,

BS_DEFAULT

A BS_DEFAULT pushbutton is one with a thick border box. It has the same properties as a pushbutton. In addition, the user may press a BS_DEFAULT pushbutton by pressing the RETURN or ENTER key. The intention is the same for user-buttons, but the appearance of a BS_DEFAULT userbutton is application defined.

This style can be ORed with the BS_PUSHBUTTON and BS_USERBUTTON styles:

BS_HELP

The button posts a [WM_HELP](#) message rather than a [WM_COMMAND](#) message.

This style can be ORed with the BS_PUSHBUTTON style.

If both BS_HELP and BS_SYSCOMMAND are set, BS_HELP takes precedence.

BS_ICON

Places an icon instead of text on the push button control. This style works only with the BS_PUSHBUTTON style.

BS_MINIICON

This enables miniicons (half the size of normal icons) to be placed on the push button control.

BS_NOBORDER

The pushbutton is displayed without a border drawn around it. There is no other change in the pushbutton's operation.

This style can be ORed with the BS_PUSHBUTTON style.

BS_NOCURSORSELECT

The radio button does not select itself when given the focus as the result of an arrow key or tab key.

This style can be ORed with the BS_AUTORADIOBUTTON style.

BS_NOPOINTERFOCUS

Buttons with this style do not set the focus to themselves when clicked with the pointing device. This enables the cursor to stay on a control for which information is required, rather than moving to the button. This style has no effect on keyboard interaction. The tab key can still be used as usual to move the focus to the button.

This style can be ORed with any of the basic button styles.

BS_NOTEBOOKBUTTON

A notebook button is identical to a pushbutton except that when it is created as a child of a notebook page it becomes a button in the common button area of the notebook page. If the button is not in a notebook page it will be indistinguishable from a pushbutton.

BS_PUSHBUTTON

A pushbutton is a box that contains a string. When a button is pushed, by clicking the pointing device on it or pressing the spacebar when it is active, the parent window is notified.

BS_RADIOBUTTON

A radio button is similar to a check box, but is typically used in groups in which only one button at a time is checked. When a radio button is clicked or a cursor key is pressed to move within the group, it notifies its owner window. It is then up to the owner window to check the clicked radio button and uncheck all the rest, if necessary.

BS_SYSCOMMAND

The button posts a [WM_SYSCOMMAND](#) message rather than a [WM_COMMAND](#) message.

This style can be ORed with the BS_PUSHBUTTON style.

If both BS_HELP and BS_SYSCOMMAND are set, BS_HELP takes

BS_TEXT

This enables both text and a bitmap, icon, or miniicon to be placed on the push button control. This style works only with the BS_PUSHBUTTON style, and should be used in conjunction with BS_BITMAP, BS_ICON or BS_MINIICON.

BS_USERBUTTON

This is an application-definable button. The owner window of this style control receives the additional button style BN_PAINT.

BS_3STATE

A three-state check box is identical to a check box control except that its check box can be half-toned as well as the box being checked or unchecked.

When BS_ICON, BS_MINIICON or BS_BITMAP is selected, the image can be activated by specifying the image ID with the button text string. For instance, to load an icon (#define ICON_ID 300), and display it within a button, the button string is set to "#300."

When BS_ICON, BS_MINIICON or BS_BITMAP is selected along with BS_TEXT, the image can still be activated by specifying the following with a zero-terminated text string. format:

```
"#<image-id>\t<text>"
```

where:

<image-id>	resource id of the icon, miniicon or bitmap
\t	tab character
<text>	zero-terminated button text string

For example, to load an icon (#define ICON_ID 300) and display it with the button text "My Button," the button string is set to "#300\tMy Button." Notice the "\t" is used to separate the text from the image-id. The image is displayed above the text within the button.

Default Colors

The following system colors are used when the system draws button controls:

```
SYSCLR_BUTTONDEFAULT  
SYSCLR_BUTTONLIGHT  
SYSCLR_BUTTONMIDDLE  
SYSCLR_MENUTEXT  
SYSCLR_WINDOW  
SYSCLR_WINDOWFRAME.
```

Some of these defaults can be replaced by using the following presentation parameters in the application resource script file or source code:

```
PP_BACKGROUNDCOLOR  
PP_BORDERCOLOR  
PP_DISABLEDFOREGROUND  
PP_FOREGROUND  
PP_HILITEFOREGROUND.
```

Button Control Notification Messages

These messages are initiated by the button control window to notify its owner of significant events.

WM_COMMAND (in Button Controls)

WM_COMMAND (in Button Controls) - Syntax

For the cause of this message, see [WM_COMMAND](#).

For a description of the parameters, see [WM_COMMAND](#).

Button control sets *uscmd* to the button identity and *ussource* to CMDSRC_PUSHBUTTON.

WM_COMMAND (in Button Controls) - Remarks

The button control generates this message when a push button of style BS_PUSHBUTTON is pressed or when it receives a [BM_CLICK](#) message. The button control posts the message to the queue of the control owner.

WM_COMMAND (in Button Controls) - Default Processing

The default window procedure takes no action on this message, other than to set *uiReserved* to 0.

WM_COMMAND (in Button Controls) - Related Messages

WM_CONTROL (in Button Controls)

WM_CONTROL (in Button Controls) Field - id

id ([USHORT](#))
Button control identity.

WM_CONTROL (in Button Controls) Field - usnotifycode

usnotifycode ([USHORT](#))
Notification code.

The notification code BN_PAINT is only generated when the button control has a style of BS_USERBUTTON.

The button control uses these notification codes:

BN_CLICKED The button has been pressed.

BN_DBLCLICKED The button has been double-clicked.

BN_PAINT The button requires painting, using one of the following draw states:

BDS_DISABLED The disabled state of the button requires painting.

BDS_HILITED The highlighted state of the button requires painting.

BDS_DEFAULT The default state of the button requires painting.

WM_CONTROL (in Button Controls) Field - flcontrolspect

flcontrolspect ([ULONG](#))
Control-specific information.

When *usnotifycode* is BN_PAINT this parameter is a pointer to a [USERBUTTON](#) structure, otherwise this parameter is the window handle of the button control.

WM_CONTROL (in Button Controls) Return Value - ulReserved

ulReserved ([ULONG](#))
Reserved value, should be 0.

WM_CONTROL (in Button Controls) - Parameters

id ([USHORT](#))

Button control identity.

usnotifycode ([USHORT](#))

Notification code.

The notification code BN_PAINT is only generated when the button control has a style of BS_USERBUTTON.

The button control uses these notification codes:

BN_CLICKED

The button has been pressed.

BN_DBLCLICKED

The button has been double-clicked.

BN_PAINT

The button requires painting, using one of the following draw states:

BDS_DISABLED

The disabled state of the button requires painting.

BDS_HILITED

The highlighted state of the button requires painting.

BDS_DEFAULT

The default state of the button requires painting.

flcontrolspect ([ULONG](#))

Control-specific information.

When *usnotifycode* is BN_PAINT this parameter is a pointer to a [USERBUTTON](#) structure, otherwise this parameter is the window handle of the button control.

ulReserved ([ULONG](#))

Reserved value, should be 0.

WM_CONTROL (in Button Controls) - Syntax

For the cause of this message, see [WM_CONTROL](#).

```
param1
    USHORT id           /* Button control identity. */
    USHORT usnotifycode /* Notification code. */

param2
    ULONG flcontrolspect /* Control-specific information. */
```

WM_CONTROL (in Button Controls) - Remarks

The button control generates this message and sends it to its owner, informing the owner of this event, when:

- Its style is not BS_PUSHBUTTON and the button is pressed.
- It receives a [BM_CLICK](#) message.
- Its style is BS_USERBUTTON and the button is clicked or double clicked.

WM_CONTROL (in Button Controls) - Default Processing

The default window procedure takes no action on this message, other than to set *uiReserved* to 0.

WM_HELP (in Button Controls)

WM_HELP (in Button Controls) - Syntax

For the cause of this message, see [WM_HELP](#).

For a description of the parameters, see [WM_HELP](#).

Button control sets *uscmd* to the button identity.

WM_HELP (in Button Controls) - Remarks

This message is identical to a [WM_COMMAND](#) message, but implies that the application should respond to this message by displaying help information.

The button control generates this message and posts it to the queue of its owner, if it has the style of BS_HELP and a push button is pressed, or when it receives a [BM_CLICK](#) message.

WM_HELP (in Button Controls) - Default Processing

The default window procedure sends this message to the parent window, if it exists and is not the desktop. Otherwise, it sets *uReserved* to 0.

WM_SYSCOMMAND

WM_SYSCOMMAND - Syntax

For the cause of this message, see [WM_SYSCOMMAND](#).

For a description of the parameters, see [WM_SYSCOMMAND](#).

Button control sets *uscmd* to the button identity.

WM_SYSCOMMAND - Remarks

If the button control is specified with a style of BS_SYSCOMMAND but not with BS_HELP, the button control generates this message and posts it to the queue of its owner when a push button is pressed, or when it receives a [BM_CLICK](#) message.

WM_SYSCOMMAND - Default Processing

The default window procedure takes no action on this message, other than to set *ulReserved* to 0.

Button Control Window Messages

This section describes the Button Control Window Procedure actions on receiving the following messages.

BM_AUTOSIZE

BM_AUTOSIZE Field - ulReserved

ulReserved ([ULONG](#))
Reserved value, should be 0.

BM_AUTOSIZE Field - ulReserved

ulReserved ([ULONG](#))

Reserved value, should be 0.

BM_AUTOSIZE Return Value - rc

rc (BOOL)

Success indicator.

TRUE

The button was automatically sized according to the size of its contents.

FALSE

The button was not automatically sized.

BM_AUTOSIZE - Parameters

ulReserved (ULONG)

Reserved value, should be 0.

ulReserved (ULONG)

Reserved value, should be 0.

rc (BOOL)

Success indicator.

TRUE

The button was automatically sized according to the size of its contents.

FALSE

The button was not automatically sized.

BM_AUTOSIZE - Syntax

This message causes a button to be resized based on the size of its contents.

```
param1
    ULONG ulReserved /* Reserved value, should be 0. */

param2
    ULONG ulReserved /* Reserved value, should be 0. */
```

BM_AUTOSIZE - Remarks

This message is used by the notebook control to size buttons placed in the common area. If the button control has a style of BS_NOTEBOOKBUTTON, it responds to this message by setting rc as appropriate. If the button has any other style, the button control

takes no action other than to set *rc* to FALSE.

BM_AUTOSIZE - Default Processing

The default window procedure does not expect to receive this message and therefore takes no action on it, except to set *rc* to the default value of FALSE.

BM_AUTOSIZE - Topics

BM_CLICK

BM_CLICK Field - usUp

- usUp** ([USHORT](#))
Up and down indicator.
- | | |
|-------|---------------------------------------|
| TRUE | Perform the default upclick action |
| FALSE | Perform the default downclick action. |

BM_CLICK Field - ulReserved

- ulReserved** ([ULONG](#))
Reserved value, should be 0.

BM_CLICK Return Value - ulReserved

ulReserved ([ULONG](#))
Reserved value, should be 0.

BM_CLICK - Parameters

usUp ([USHORT](#))
Up and down indicator.

TRUE	Perform the default upclick action
FALSE	Perform the default downclick action.

ulReserved ([ULONG](#))
Reserved value, should be 0.

ulReserved ([ULONG](#))
Reserved value, should be 0.

BM_CLICK - Syntax

An application sends this message to cause the effect of the operator clicking a push button.

```
param1
    USHORT    usUp        /* Up and down indicator. */

param2
    ULONG     ulReserved  /* Reserved value, should be 0. */
```

BM_CLICK - Remarks

The button control responds to this message by taking the action that occurs if the button is clicked by the operator. This causes the following messages to be generated:

- A [WM_HELP](#) (in [Button Controls](#)) message, if the button has a style of BS_HELP.
- A [WM_SYSCOMMAND](#) message, if the button has a style of BS_PUSHBUTTON and a style of BS_SYSCOMMAND and not a style of BS_HELP.
- A [WM_COMMAND](#) (in [Button Controls](#)) message, if the button has a style of BS_PUSHBUTTON but not a style of BS_SYSCOMMAND and not a style of BS_HELP.
- A [WM_CONTROL](#) (in [Button Controls](#)) message, whose *usnotifycode* is set to BN_CLICKED, if the button has a style of BS_USERBUTTON, BS_PUSHBUTTON, BS_CHECKBOX, or BS_3STATE, and not a style of BS_SYSCOMMAND or BS_HELP.

BM_CLICK - Default Processing

The default window procedure does not expect to receive this message and therefore takes no action on it, other than to set *ulReserved* to the default value of 0.

BM_CLICK - Topics

BM_QUERYCHECK

BM_QUERYCHECK Field - ulReserved

ulReserved ([ULONG](#))
Reserved value, should be 0.

BM_QUERYCHECK Field - ulReserved

ulReserved ([ULONG](#))
Reserved value, should be 0.

BM_QUERYCHECK Return Value - usCheck

usCheck ([USHORT](#))
Check indicator.

0	The button control is in unchecked state.
---	---

- | | |
|---|---|
| 1 | The button control is in checked state. |
| 2 | The button control is in indeterminate state. |

BM_QUERYCHECK - Parameters

ulReserved ([ULONG](#))
Reserved value, should be 0.

ulReserved ([ULONG](#))
Reserved value, should be 0.

usCheck ([USHORT](#))
Check indicator.

- | | |
|---|---|
| 0 | The button control is in unchecked state. |
| 1 | The button control is in checked state. |
| 2 | The button control is in indeterminate state. |

BM_QUERYCHECK - Syntax

This message returns the checked state of a button control.

```
param1
    ULONG    ulReserved /* Reserved value, should be 0. */

param2
    ULONG    ulReserved /* Reserved value, should be 0. */
```

BM_QUERYCHECK - Remarks

The button control responds to this message, if it has a style of BS_CHECKBOX, BS_AUTOCHECKBOX, BS_RADIOBUTTON, BS_AUTORADIOBUTTON, BS_3STATE, or BS_AUTO3STATE, by setting *usCheck* as appropriate.

If the button has any other style, the button control takes no action other than to set *usCheck* to 0.

BM_QUERYCHECK - Default Processing

The default window procedure does not expect to receive this message and therefore takes no action on it, other than to set *usCheck* to the default value of 0.

BM_QUERYCHECKINDEX

BM_QUERYCHECKINDEX Field - ulReserved

ulReserved ([ULONG](#))
Reserved value, should be 0.

BM_QUERYCHECKINDEX Field - ulReserved

ulReserved ([ULONG](#))
Reserved value, should be 0.

BM_QUERYCHECKINDEX Return Value - sIndex

sIndex ([SHORT](#))
Radio-button index.

-1	No radio button of the group is checked, or this button control does not have the style BS_RADIOBUTTON or BS_AUTORADIOBUTTON.
Other	Zero-based index of the checked radio button of the group.

BM_QUERYCHECKINDEX - Parameters

ulReserved ([ULONG](#))

Reserved value, should be 0.

ulReserved ([ULONG](#))

Reserved value, should be 0.

sIndex ([SHORT](#))

Radio-button index.

-1

No radio button of the group is checked, or this button control does not have the style BS_RADIOBUTTON or BS_AUTORADIOBUTTON.

Other

Zero-based index of the checked radio button of the group.

BM_QUERYCHECKINDEX - Syntax

This message returns the zero-based index of a checked radio button.

```
param1
    ULONG ulReserved /* Reserved value, should be 0. */
param2
    ULONG ulReserved /* Reserved value, should be 0. */
```

BM_QUERYCHECKINDEX - Remarks

The button control responds to this message by setting *sIndex* as appropriate.

This message may be sent to any radio button or autoradio button in a group of buttons. For details of the WS_GROUP style, see [Window Styles](#).

BM_QUERYCHECKINDEX - Default Processing

The default window procedure does not expect to receive this message and therefore takes no action on it, other than to set *sIndex* to the default value of 0.
